Complex bit access types are encoded to fit into small table cells. Table 26-23 shows the codes that are used for access types in this section.

Table 26-23. EPWM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

26.16.2.1 TBCTL Register (Offset = 0h) [reset = 83h]

TBCTL is shown in Figure 26-92 and described in Table 26-24.

Return to the Summary Table.

Time Base Control Register

Figure 26-92. TBCTL Register

15	14	13	12	11	10	9	8
FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV	
R/W-0h		R/W-0h	R/W-0h			R/W-1h	
7	6	5	4	3	2	1	0
HSPCLKDIV	SWFSYNC	RESERVED		PRDLD	PHSEN	CTRMODE	
R/W-1h	R-0/W1S-0h	R-0h		R/W-0h	R/W-0h	R/W-3h	

Table 26-24. TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events 00: Stop after the next time-base counter increment or decrement 01: Stop when counter completes a whole cycle: - Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) - Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) - Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) 1x: Free run Reset type: SYSRSn
13	PHSDIR	R/W	0h	Phase Direction Bit This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0: Count down after the synchronization event. 1: Count up after the synchronization event. Reset type: SYSRSn
12-10	CLKDIV	R/W	0h	Time Base Clock Pre-Scale Bits These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV): 000: /1 (default on reset) 001: /2 010: /4 011: /8 100: /16 101: /32 110: /64 111: /128 Reset type: SYSRSn

Table 26-24. TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time Base Clock Pre-Scale Bits These bits determine part of the time-base clock prescale value. TBCLK = EPWMCLK / (HSPCLKDIV x CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 000: /1 001: /2 (default on reset) 010: /4 011: /6 100: /8 101: /10 110: /12 111: /14 Reset type: SYSRSn
6	SWFSYNC	R-0/W1S	0h	Software Forced Sync Pulse 0: Writing a 0 has no effect and reads always return a 0. 1: Writing a 1 forces a one-time synchronization pulse to be generated. SWFSYNC can be enabled to affect EPWMxSYNCO by setting the EPWMSYNCOUTEN.SWEN bit. Reset type: SYSRSn
5-4	RESERVED	R	0h	Reserved
3	PRDLD	R/W	0h	Active Period Reg Load from Shadow Select 0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. A write/read to the TBPRD register accesses the shadow register. 1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register. Reset type: SYSRSn
2	PHSEN	R/W	0h	Counter Reg Load from Phase Reg Enable 0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS). 1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCI input signal occurs or a software-forced sync signal, see bit 6. Reset type: SYSRSn
1-0	CTRMODE	R/W	3h	Counter Mode The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 00: Up-count mode 01: Down-count mode 10: Up-down count mode 11: Freeze counter operation (default on reset) Reset type: SYSRSn

26.16.2.2 TBCTL2 Register (Offset = 1h) [reset = 0h]

TBCTL2 is shown in Figure 26-93 and described in Table 26-25.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
3-2	LOADDMODE	R/W	0h	Active Counter-Compare D (CMPD) Load from Shadow Select Mode 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Freeze (no loads possible) Note: Has no effect in Immediate mode. Reset type: SYSRSn
1-0	LOADCMODE	R/W	0h	Active Counter-Compare C (CMPC) Load from Shadow Select Mode 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Freeze (no loads possible) Note: Has no effect in Immediate mode. Reset type: SYSRSn

26.16.2.10 DBCTL Register (Offset = Ch) [reset = 0h]

DBCTL is shown in Figure 26-101 and described in Table 26-33.

Return to the Summary Table.

Dead-Band Generator Control Register

Figure 26-101. DBCTL Register

15	14	13	12	11	10	9	8
HALFCYCLE	DEDB_MODE	OUTSWAP		SHDWDBFED MODE	SHDWDBRED MODE	LOADFEDMODE	
R/W-0h	R/W-0h	R/W-0h		R/W-0h	R/W-0h	R/W-0h	
7	6	5	4	3	2	1	0
LOADREDMODE		IN_MODE		POLSEL		OUT_MODE	
R/W-0h		R/W-0h		R/W-0h		R/W-0h	

Table 26-33. DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit 0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2. Reset type: SYSRSn
14	DEDB_MODE	R/W	0h	Dead Band Dual-Edge B Mode Control (S8 switch) 0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only. 1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath otherwise, OutA will be invalid. Reset type: SYSRSn
13-12	OUTSWAP	R/W	0h	Dead Band Output Swap Control Bit 13 controls the S6 switch and bit 12 controls the S7 switch. 00: OutA and OutB signals are as defined by OUT-MODE bits. 01: OutA = A-path as defined by OUT-MODE bits. OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). 10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = B-path as defined by OUT-MODE bits. 11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). Reset type: SYSRSn
11	SHDWDBFEDMODE	R/W	0h	FED Dead-Band Load Mode 0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate "FED dead-band action." 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn

Table 26-33. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	SHDWDBREDMODE	R/W	0h	RED Dead-Band Load Mode 0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate "RED dead-band action." 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn
9-8	LOADFEDMODE	R/W	0h	Active DBFED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
7-6	LOADREDMODE	R/W	0h	Active DBRED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
5-4	IN_MODE	R/W	0h	Dead-Band Input Mode Control Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal. Reset type: SYSRSn
3-2	POLSEL	R/W	0h	Polarity Select Control Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes. 00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 01: Active low complementary (ALC) mode. EPWMxA is inverted. 10: Active high complementary (AHC). EPWMxB is inverted. 11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted. Reset type: SYSRSn

Table 26-33. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OUT_MODE	R/W	0h	Dead-Band Output Mode Control Bit 1 controls the S1 switch and bit 0 controls the S0 switch. 00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect. 01: Apath = InA (delay is by-passed for A signal path) Bpath = FED (Falling Edge Delay in B signal path) 10: Apath = RED (Rising Edge Delay in A signal path) Bpath = InB (delay is by-passed for B signal path) 11: DBM is fully enabled (i.e. both RED and FED active) Reset type: SYSRSn

26.16.2.11 DBCTL2 Register (Offset = Dh) [reset = 0h]

DBCTL2 is shown in Figure 26-102 and described in Table 26-34.

Return to the Summary Table.

Table 26-40. HRCNFG Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	RESERVED	R/W	0h	Reserved
13	RESERVED	R-0	0h	Reserved
12-11	HRLOADB	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPBHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Reserved Reset type: SYSRSn
10	CTLMODEB	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPBHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
9-8	EDGMODEB	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPBHR) 10: MEP control of falling edge (CMPBHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn
7	SWAPAB	R/W	0h	Swap ePWM A & B Output Signals This bit enables the swapping of the A & B signal outputs. The selection is as follows: 0: ePWMxA and ePWMxB outputs are unchanged. 1: ePWMxA signal appears on ePWMxB output and ePWMxB signal appears on ePWMxA output. Reset type: SYSRSn

Table 26-40. HRCNFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	AUTOCONV	R/W	0h	Auto Convert Delay Line Value Selects whether the fractional duty cycle/period/phase in the CMPAHR/TBPRDHR/TBPHSHR register is automatically scaled by the MEP scale factor in the HRMSTEP register or manually scaled by calculations in application software. The SFO library function automatically updates the HRMSTEP register with the appropriate MEP scale factor. 0: Automatic HRMSTEP scaling is disabled. 1: Automatic HRMSTEP scaling is enabled. If application software is manually scaling the fractional duty cycle, or phase (i.e. software sets CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor)<<8 + 0x080 for duty cycle), then this mode must be disabled. Reset type: SYSRSn
5	SELOUTB	R/W	0h	EPWMxB Output Select Bit This bit selects which signal is output on the ePWMxB channel output. The inversion will take the high resolution mode into account and the inverted signal will contain any high resolution modification. The inversion takes place as the last step in modifying the ePWMxB signal. 0: ePWMxB output is normal. 1: ePWMxB output is inverted version of ePWMxA signal. Reset type: SYSRSn
4-3	HRLOAD	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPAHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Reserved Reset type: SYSRSn
2	CTLMODE	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPAHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
1-0	EDGMODE	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPAHR) 10: MEP control of falling edge (CMPAHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn

26.16.2.18 HRPWR Register (Offset = 21h) [reset = 0h]

HRPWR is shown in Figure 26-109 and described in Table 26-41.

Return to the Summary Table.

HRPWM Power Register

This register is only accessible on EPWM modules with HRPWM capabilities.

3	RESERVED	R/W	0h	Reserved
2	TBPHSHRLOADE	R/W	0h	TBPHSHR Load Enable This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution. 0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event: 1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PHSEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature. This bit and the TBCTL[PHSEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled. Reset type: SYSRSn
1	PWMSYNCSEL	R/W	0h	PWMSYNC Source Select Bit: This bit selects the source for the EPWMSYNCPER signal that goes to the CMPSS and GPDAC: 0 CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 1 CTR = zero: Time-base counter equal to zero (TBCTR = 0x00) Reset type: SYSRSn

Table 26-44. HRPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	HRPE	R/W	0h	High Resolution Period Enable Bit 0: High resolution period feature disabled. In this mode the ePWM behaves as a Type 0 ePWM. 1: High resolution period enabled. In this mode the HRPWM module can control high-resolution of both the duty and frequency. When high-resolution period is enabled, TBCTL[CTRMODE] = 0,1 (down-count mode) is not supported. Reset type: SYSRSn

26.16.2.22 TRREM Register (Offset = 2Eh) [reset = 0h]

TRREM is shown in Figure 26-113 and described in Table 26-45.

Return to the Summary Table.

Translator High Resolution Remainder Register
This register is only accessible on EPWM modules with HRPWM capabilities.

Figure 26-113. TRREM Register

TBPRD							
R/W-0h							
7	6	5	4	3	2	1	0
TBPRD							
R/W-0h							

Table 26-61. TBPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	Time Base Period Register These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. - If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. - If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - The active and shadow registers share the same memory map address. Reset type: SYSRSn

26.16.2.39 CMPA Register (Offset = 6Ah) [reset = 0h]

CMPA is shown in Figure 26-130 and described in Table 26-62.

Return to the Summary Table.

Counter Compare A Register

Figure 26-130. CMPA Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPA																CMPAHR															
R/W-0h																R/W-0h															

Table 26-62. CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	CMPA	R/W	0h	Compare A Register The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include: - Do nothing the event is ignored. - Clear: Pull the EPWMxA and/or EPWMxB signal low - Set: Pull the EPWMxA and/or EPWMxB signal high - Toggle the EPWMxA and/or EPWMxB signal Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. - If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. - Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. - If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - In either mode, the active and shadow registers share the same memory map address. Reset type: SYSRSn
15-0	CMPAHR	R/W	0h	Compare A HRPWM Extension Register The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register. The lower 8 bits in this register are ignored Reset type: SYSRSn

26.16.2.40 CMPB Register (Offset = 6Ch) [reset = 0h]

CMPB is shown in Figure 26-131 and described in Table 26-63.

Return to the Summary Table.

Compare B Register

Figure 26-131. CMPB Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPB																CMPBHR

Table 26-66. GLDCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-2	RESERVED	R-0	0h	Reserved
1	GFRCLD	R-0/W1S	0h	Force Load Event in One Shot Mode 0: Writing of 0 will be ignored. Always reads back a 0. 1: Force one load event at the input of the event pre-scale counter as shown in the diagram below. This bit is intended to be used for testing and/or software force loading of the events in global load mode. Reset type: SYSRSn
0	OSHTLD	R-0/W1S	0h	Enable Reload Event in One Shot Mode 0: Writing of 0 will be ignored. Always reads back a 0. 1: Turns the one shot latch condition ON. Upon occurrence of a chosen load strobe, one shadow to active reload occurs and the latch will be cleared. Hence writing 1 to this bit would allow one load strobe event to pass through and block further strobe events. Reset type: SYSRSn

26.16.2.44 SWVDELVAL Register (Offset = 77h) [reset = 0h]

SWVDELVAL is shown in Figure 26-135 and described in Table 26-67.

Return to the Summary Table.

6	DCBEVT2	R	0h	Latched Status Flag for Digital Compare Output B Event 2 0: Indicates no trip event has occurred on DCBEVT2 1: Indicates a trip event has occurred for the event defined for DCBEVT2 Reset type: SYSRSn
5	DCBEVT1	R	0h	Latched Status Flag for Digital Compare Output B Event 1 0: Indicates no trip event has occurred on DCBEVT1 1: Indicates a trip event has occurred for the event defined for DCBEVT1 Reset type: SYSRSn
4	DCAEVT2	R	0h	Latched Status Flag for Digital Compare Output A Event 2 0: Indicates no trip event has occurred on DCAEVT2 1: Indicates a trip event has occurred for the event defined for DCAEVT2 Reset type: SYSRSn
3	DCAEVT1	R	0h	Latched Status Flag for Digital Compare Output A Event 1 0: Indicates no trip event has occurred on DCAEVT1 1: Indicates a trip event has occurred for the event defined for DCAEVT1 Reset type: SYSRSn
2	OST	R	0h	Latched Status Flag for A One-Shot Trip Event 0: No one-shot trip event has occurred. 1: Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn
1	CBC	R	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0: No cycle-by-cycle trip event has occurred. 1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

Table 26-75. TZFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	INT	R	0h	Latched Trip Interrupt Status Flag 0: Indicates no interrupt has been generated. 1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition. No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

26.16.2.53 TZCBCFLG Register (Offset = 94h) [reset = 0h]

TZCBCFLG is shown in Figure 26-144 and described in Table 26-76.

Table 26-83. ETPS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	SOCBCNT	R	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Counter Register These bits indicate how many selected ETSEL[SOCBSEL] events have occurred: 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn
13-12	SOCBPRD	R/W	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Period Select These bits determine how many selected ETSEL[SOCBSEL] events need to occur before an EPWMxSOCB pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCBEN] = 1). The SOCB pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCB] = 1). Once the SOCB pulse is generated, the ETPS[SOCBCNT] bits will automatically be cleared. 00: Disable the SOCB event counter. No EPWMxSOCB pulse will be generated 01: Generate the EPWMxSOCB pulse on the first event: ETPS[SOCBCNT] = 0,1 10: Generate the EPWMxSOCB pulse on the second event: ETPS[SOCBCNT] = 1,0 11: Generate the EPWMxSOCB pulse on the third event: ETPS[SOCBCNT] = 1,1 Reset type: SYSRSn
11-10	SOCACNT	R	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Counter Register These bits indicate how many selected ETSEL[SOCASEL] events have occurred: 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn

Table 26-83. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-8	SOCAPRD	R/W	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCAEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared. 00: Disable the SOCA event counter. No EPWMxSOCA pulse will be generated 01: Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1 10: Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0 11: Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1 Reset type: SYSRSn
7-6	RESERVED	R-0	0h	Reserved
5	SOCPSSEL	R/W	0h	EPWMxSOC A/B Pre-Scale Selection Bits 0: Selects ETPS [SOCACNT/SOCBCNT] and [SOCAPRD/SOCBPRD] registers to determine frequency of events (interrupt once every 0-3 events). 1: Selects ETSOCPS [SOCACNT2/SOCBCNT2] and [SOCAPRD2/SOCBPRD2] registers to determine frequency of events (interrupt once every 0-15 events). Reset type: SYSRSn
4	INTPSSEL	R/W	0h	EPWMxINTn Pre-Scale Selection Bits 0: Selects ETPS [INTCNT, and INTPRD] registers to determine frequency of events (interrupt once every 0-3 events). 1: Selects ETINTPS [INTCNT2, and INTPRD2] registers to determine frequency of events (interrupt once every 0-15 events). Reset type: SYSRSn
3-2	INTCNT	R	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD]. 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn

Table 26-83. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 00: Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 01: Generate an interrupt on the first event INTCNT = 01 (first event) 10: Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 11: Generate interrupt on ETPS[INTCNT] = 1,1 (third event) Reset type: SYSRSn

26.16.2.61 ETFLG Register (Offset = A8h) [reset = 0h]

ETFLG is shown in Figure 26-152 and described in Table 26-84.

Return to the Summary Table.

RESERVED						SHDWMODE	CAPE
R-0-0h						R/W-0h	R/W-0h

Table 26-95. DCCAPCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	CAPMODE	R/W	0h	Counter Capture Mode 0: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs, further trip (capture) events are ignored until the next PRD_eq or CNT_zero event (as selected by the PULSESEL bit in the DCFCTL register) re-triggers the capture mechanism. If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value. If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value. 1: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs - it will set the CAPSTS flag and further trip (capture) events are ignored until this bit is cleared. CAPSTS can be cleared by writing to CAPCLR bit in DCCAPCTL register and it re-triggers the capture mechanism. If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value. If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value. Reset type: SYSRSn
14	CAPCLR	R-0/W1S	0h	DC Capture Latched Status Clear Flag 0: Writing a 0 has no effect. 1: Writing a 1 will clear this CAPSTS (set) condition. Reset type: SYSRSn
13	CAPSTS	R	0h	Latched Status Flag for Capture Event 0: No DC capture event occurred. 1: A DC capture event has occurred. Reset type: SYSRSn
12-2	RESERVED	R-0	0h	Reserved

Table 26-95. DCCAPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SHDWMODE	R/W	0h	TBCTR Counter Capture Shadow Select Mode 0: Enable shadow mode. The DCCAP active register is copied to shadow register on a TBCTR = TBPRD or TBCTR = zero event as defined by the DCFCTL[PULSESEL] bit. CPU reads of the DCCAP register will return the shadow register contents. 1: Active Mode. In this mode the shadow register is disabled. CPU reads from the DCCAP register will always return the active register contents. Reset type: SYSRSn
0	CAPE	R/W	0h	TBCTR Counter Capture Enable/Disable 0: Disable the time-base counter capture. 1: Enable the time-base counter capture. Reset type: SYSRSn

26.16.2.73 DCFOFFSET Register (Offset = C9h) [reset = 0h]

DCFOFFSET is shown in Figure 26-164 and described in Table 26-96.

Return to the Summary Table.

Digital Compare Filter Offset Register

7	6	5	4	3	2	1	0
DCFOFFSET							
R/W-0h							

Table 26-96. DCFOFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCFOFFSET	R/W	0h	Blanking Window Offset These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted. Reset type: SYSRSn

26.16.2.74 DCFOFFSETCNT Register (Offset = CAh) [reset = 0h]

DCFOFFSETCNT is shown in Figure 26-165 and described in Table 26-97.

Return to the Summary Table.

DCFOFFSETCNT							
R-0h							

Table 26-97. DCFOFFSETCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCFOFFSETCNT	R	0h	Blanking Offset Counter These 16-bits are read only and indicate the current value of the offset counter. The counter counts down to zero and then stops until it is re-loaded on the next period or zero event as defined by the DCFCTL[PULSESEL] bit. The offset counter is not affected by the free/soft emulation bits. That is, it will always continue to count down if the device is halted by a emulation stop. Reset type: SYSRSn

26.16.2.75 DCFWINDOW Register (Offset = CBh) [reset = 0h]

DCFWINDOW is shown in Figure 26-166 and described in Table 26-98.

Return to the Summary Table.

Digital Compare Filter Window Register

Figure 26-166. DCFWINDOW Register

DCCAP							
R-0h							
7	6	5	4	3	2	1	0
DCCAP							
R-0h							

Table 26-100. DCCAP Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCCAP	R	0h	Digital Compare Time-Base Counter Capture To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. - If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. - If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address. Reset type: SYSRSn

26.16.2.78 DCAHTRIPSEL Register (Offset = D2h) [reset = 0h]

DCAHTRIPSEL is shown in Figure 26-169 and described in Table 26-101.

Return to the Summary Table.

R-0h							

Table 26-107. VCNTVAL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	VCNTVAL	R	0h	Valley Time Base Counter Register This register reflects the captured VCNT value upon occurrence of STOPEDGE selected in VCNTCFG register. Reset type: SYSRSn

26.16.3 SYNC_SOC_REGS Registers

Table 26-108 lists the SYNC_SOC_REGS registers. All register offset addresses not listed in Table 26-108 should be considered as reserved locations and the register contents should not be modified.

Table 26-108. SYNC_SOC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SYNCSELECT	Sync Input and Output Select Register	EALLOW	Go
2h	ADCSOCOUTSELECT	External ADC (Off Chip) SOC Select Register	EALLOW	Go
4h	SYNCSOCLOCK	SYNCSEL and EXTADCSOC Select Lock register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 26-109 shows the codes that are used for access types in this section.

Table 26-109. SYNC_SOC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

26.16.3.1 SYNCSELECT Register (Offset = 0h) [reset = 0h]

SYNCSELECT is shown in Figure 26-176 and described in Table 26-110.

Return to the Summary Table.

Enhanced Quadrature Encoder Pulse (eQEP)

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type-2 eQEP. See the *TMS320x28xx, 28xxx DSP Peripheral Reference Guide* (SPRU566) for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

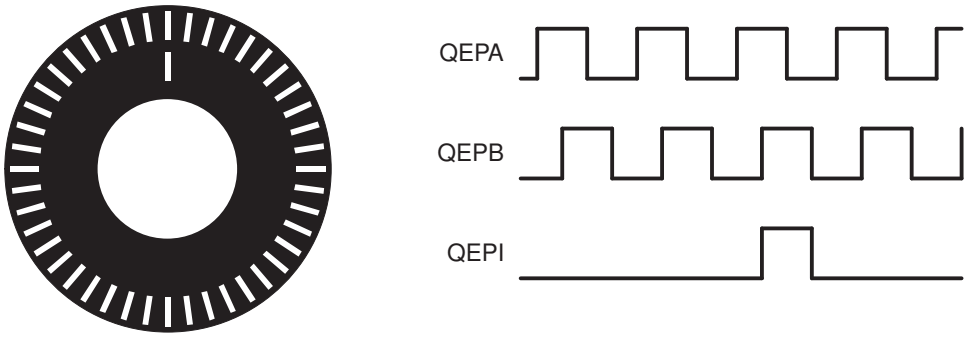
The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

Topic **Page**

27.1 Introduction

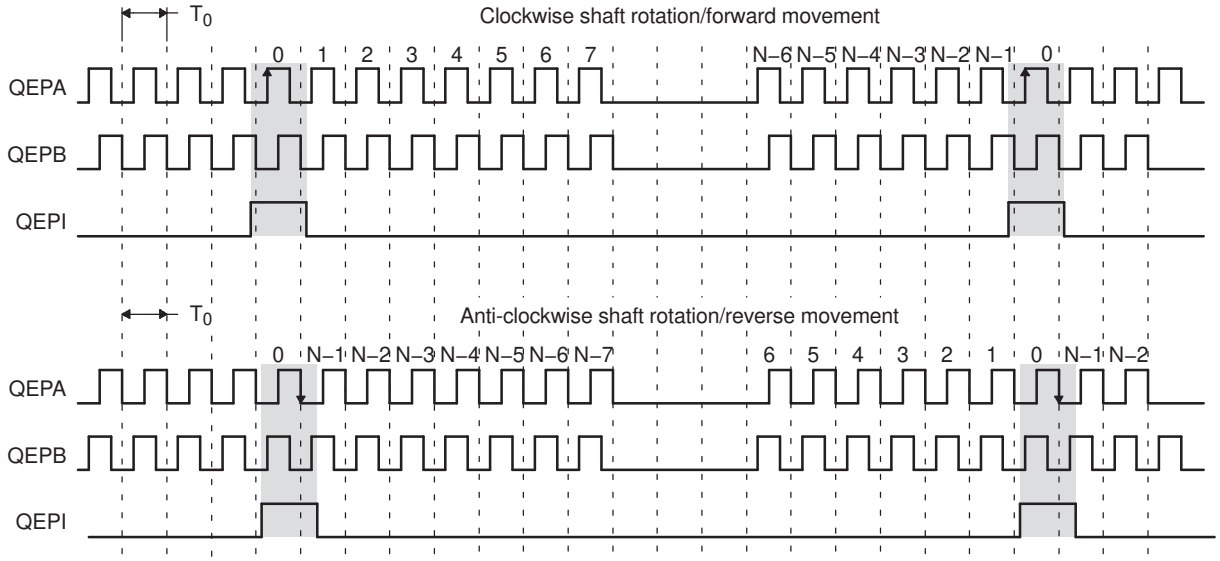
An incremental encoder disk is patterned with a track of slots along its periphery, as shown in Figure 27-1. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

Figure 27-1. Optical Encoder Disk



To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vise versa as shown in Figure 27-2.

Figure 27-2. QEP Encoder Output Signal for Forward/Reverse Movement

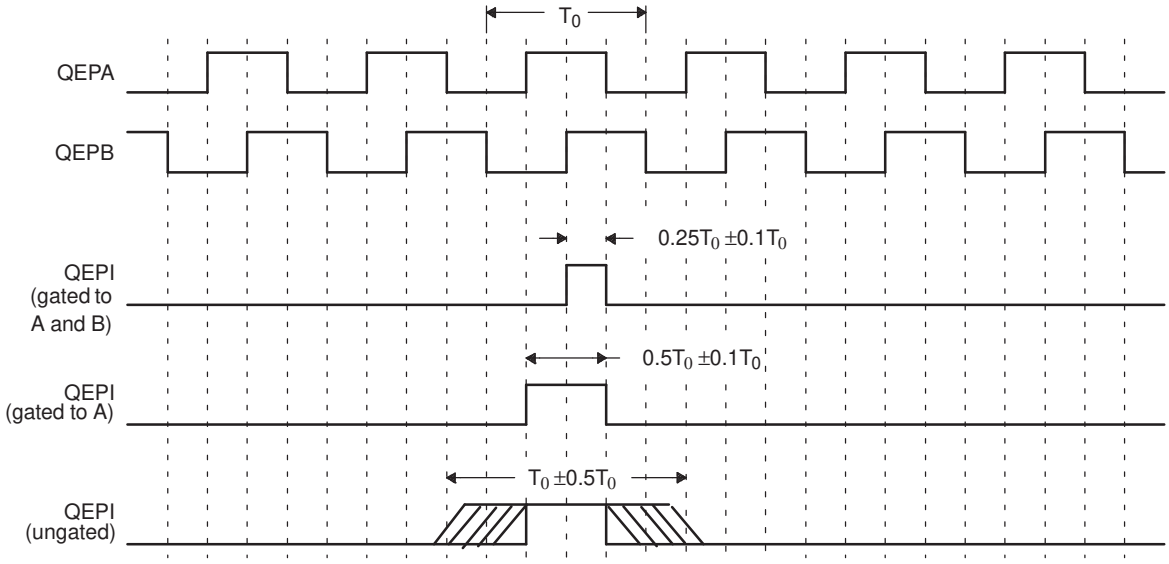


Legend: N = lines per revolution

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 27-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 27-3. Index Pulse Example



Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (5)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (6)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k-1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k-1"

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement.

Equation 5 is the conventional approach to velocity estimation and it requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 5 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 6 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 6 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 5. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 6 at low speed and have the DSP software switch over to Equation 5 when the motor speed rises above some specified threshold.

27.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured via the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode should not be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

27.3 Description

This section provides the eQEP inputs, memory map, and functional description.

27.3.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYSCLK prior to entering the module. The application code should enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- *QEPA/XCLK and QEPB/XDIR*

  These two pins can be used in quadrature-clock mode or direction-count mode.

  – *Quadrature-clock Mode*

    The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase. This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

  – *Direction-count Mode*

    In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- *QEPI: Index or Zero Marker*

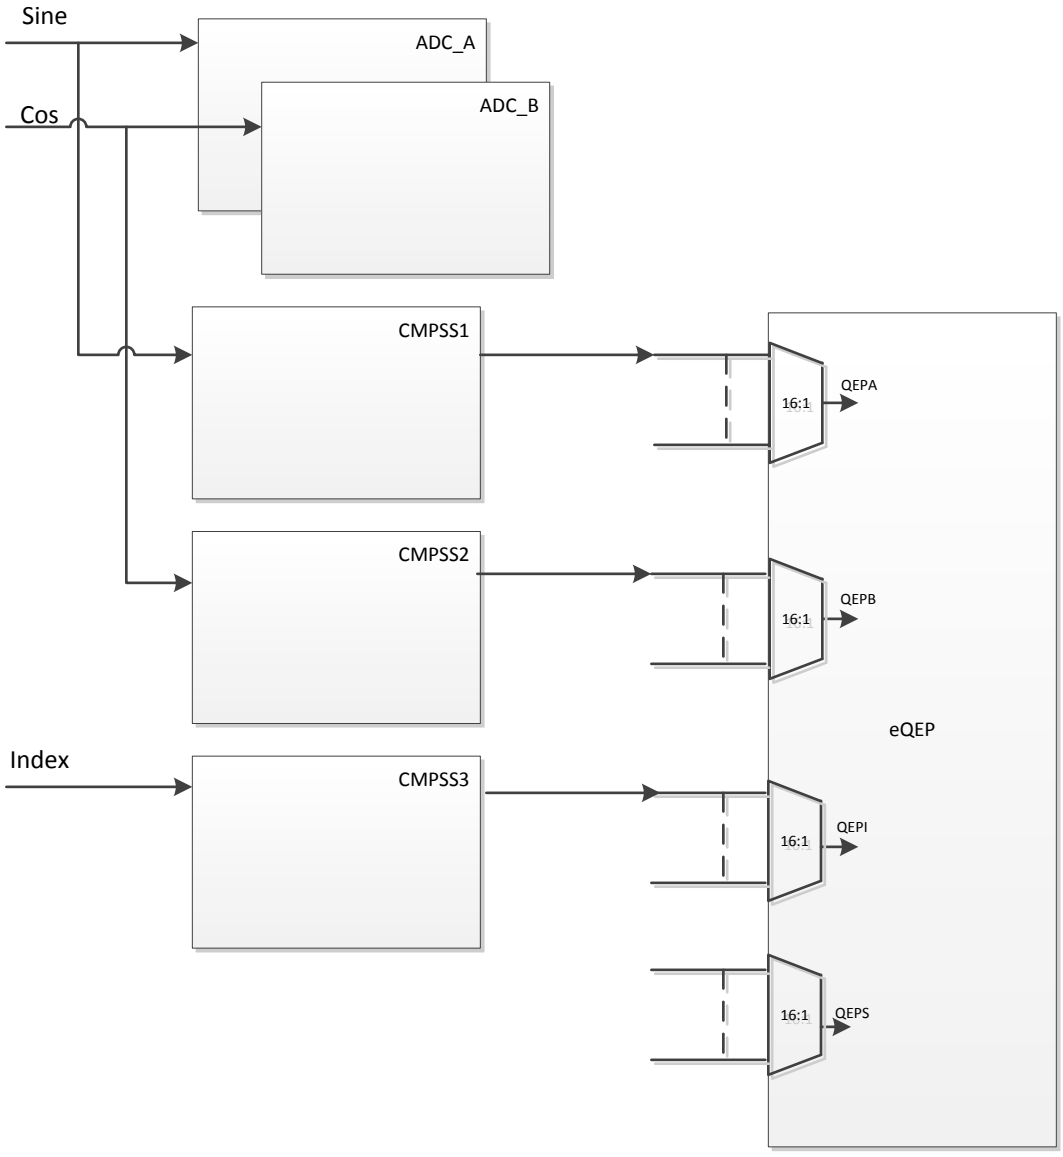
  The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- QEPS: *Strobe Input*

  This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

Input signals to the eQEP (QEPA, QEPB, QEPI and QEPS) can come from multiple sources; that is, device pin, CMPSSx, or PWMXBARx. One typical used case is if SinCos transducers are used in the motor control system to estimate the position of motor shaft and Index signal is coming from traditional rotary encoder, source of the eQEP signals (QEPA, QEPB and QEPI) can be configured as output of CMPSSx which decodes the Sin, Cos and Index signals. FigureFigure 27-4 illustrates the use case.

Figure 27-4. Using eQEP to decode signals from SinCos Transducer



Selection of the source of Input signals (QEPA, QEPB & QEPI) is user-configurable through the QEPSRCSEL register as shown in table below.

Table 27-1. EQEP Input Source Select Table

QEPSRCSEL.QEPASEL	Source for QEPA	QEPSRCSEL.QEPBSEL	Source for QEPB	QEPSRCSEL.QEPISEL	Source for QEPI
0	Device Pin	0	Device Pin	0	Device Pin
1	CMPSS1.CTRIPH	1	CMPSS1.CTRIPH	1	CMPSS1.CTRIPH
2	CMPSS2.CTRIPH	2	CMPSS2.CTRIPH	2	CMPSS2.CTRIPH
3	CMPSS3.CTRIPH	3	CMPSS3.CTRIPH	3	CMPSS3.CTRIPH
4	CMPSS4.CTRIPH	4	CMPSS4.CTRIPH	4	CMPSS4.CTRIPH
5	CMPSS5.CTRIPH	5	CMPSS5.CTRIPH	5	CMPSS5.CTRIPH
6	CMPSS6.CTRIPH	6	CMPSS6.CTRIPH	6	CMPSS6.CTRIPH
7	CMPSS7.CTRIPH	7	CMPSS7.CTRIPH	7	CMPSS7.CTRIPH
8	CMPSS8.CTRIPH	8	CMPSS8.CTRIPH	8	CMPSS8.CTRIPH
9	PWMXBAR.1	9	PWMXBAR.1	9	PWMXBAR.1
10	PWMXBAR.2	10	PWMXBAR.2	10	PWMXBAR.2
11	PWMXBAR.3	11	PWMXBAR.3	11	PWMXBAR.3
12	PWMXBAR.4	12	PWMXBAR.4	12	PWMXBAR.4
13	PWMXBAR.5	13	PWMXBAR.5	13	PWMXBAR.5
14	PWMXBAR.6	14	PWMXBAR.6	14	PWMXBAR.6
15	PWMXBAR.7	15	PWMXBAR.7	15	PWMXBAR.7

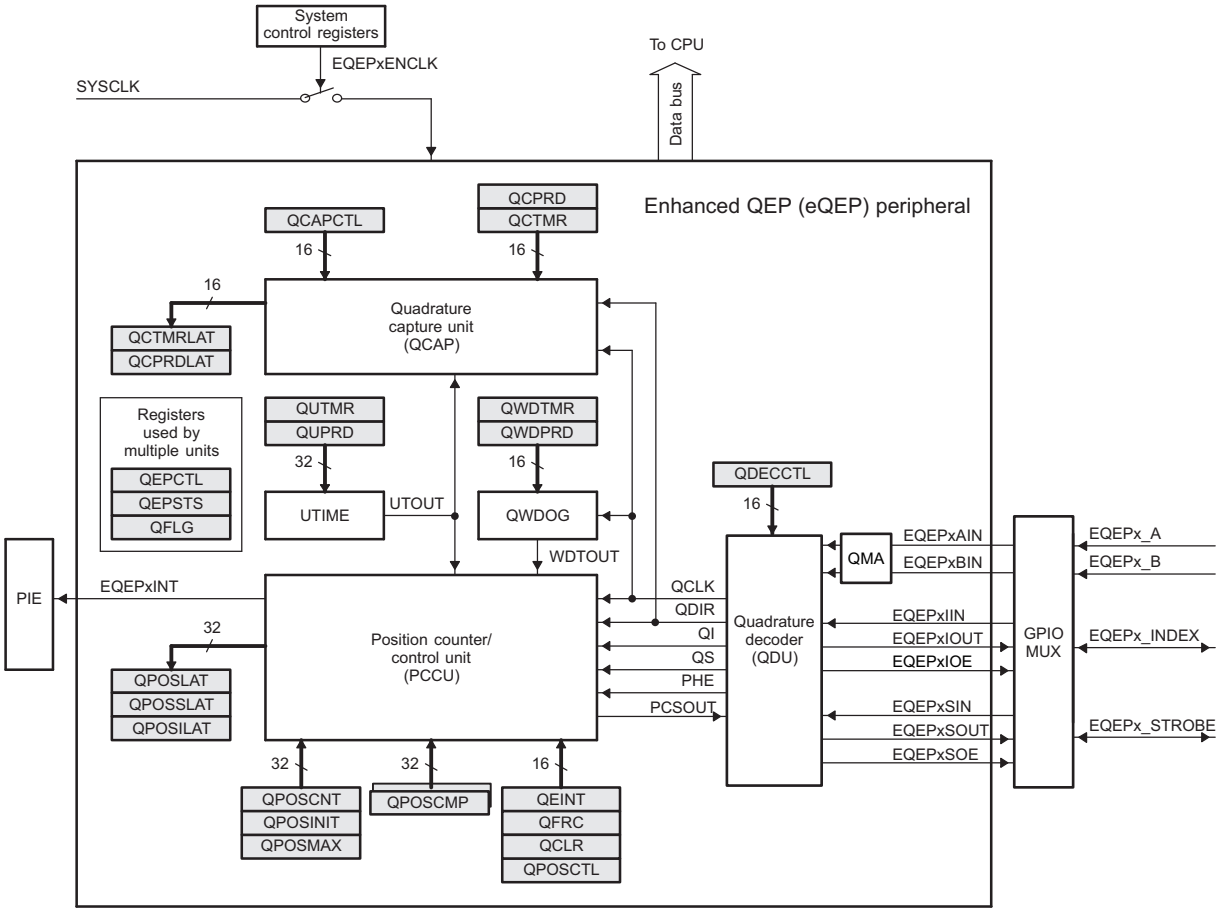
NOTE: Configuration of QEPSRCSEL register to select the source of QEPA, QEPB & QEPI signals can lead to un-expected transition on these signals, which can cause undesirable outcome if eQEP is already running. User needs to make sure that eQEP is disabled before configuring QEPSRCSEL register for input signals.

27.3.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 27-5):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)
- Quadrature Mode Adapter (QMA)

Figure 27-5. Functional Block Diagram of the eQEP Peripheral



27.3.3 eQEP Memory Map

Table 27-2 lists the registers with their memory locations, sizes, and reset values.

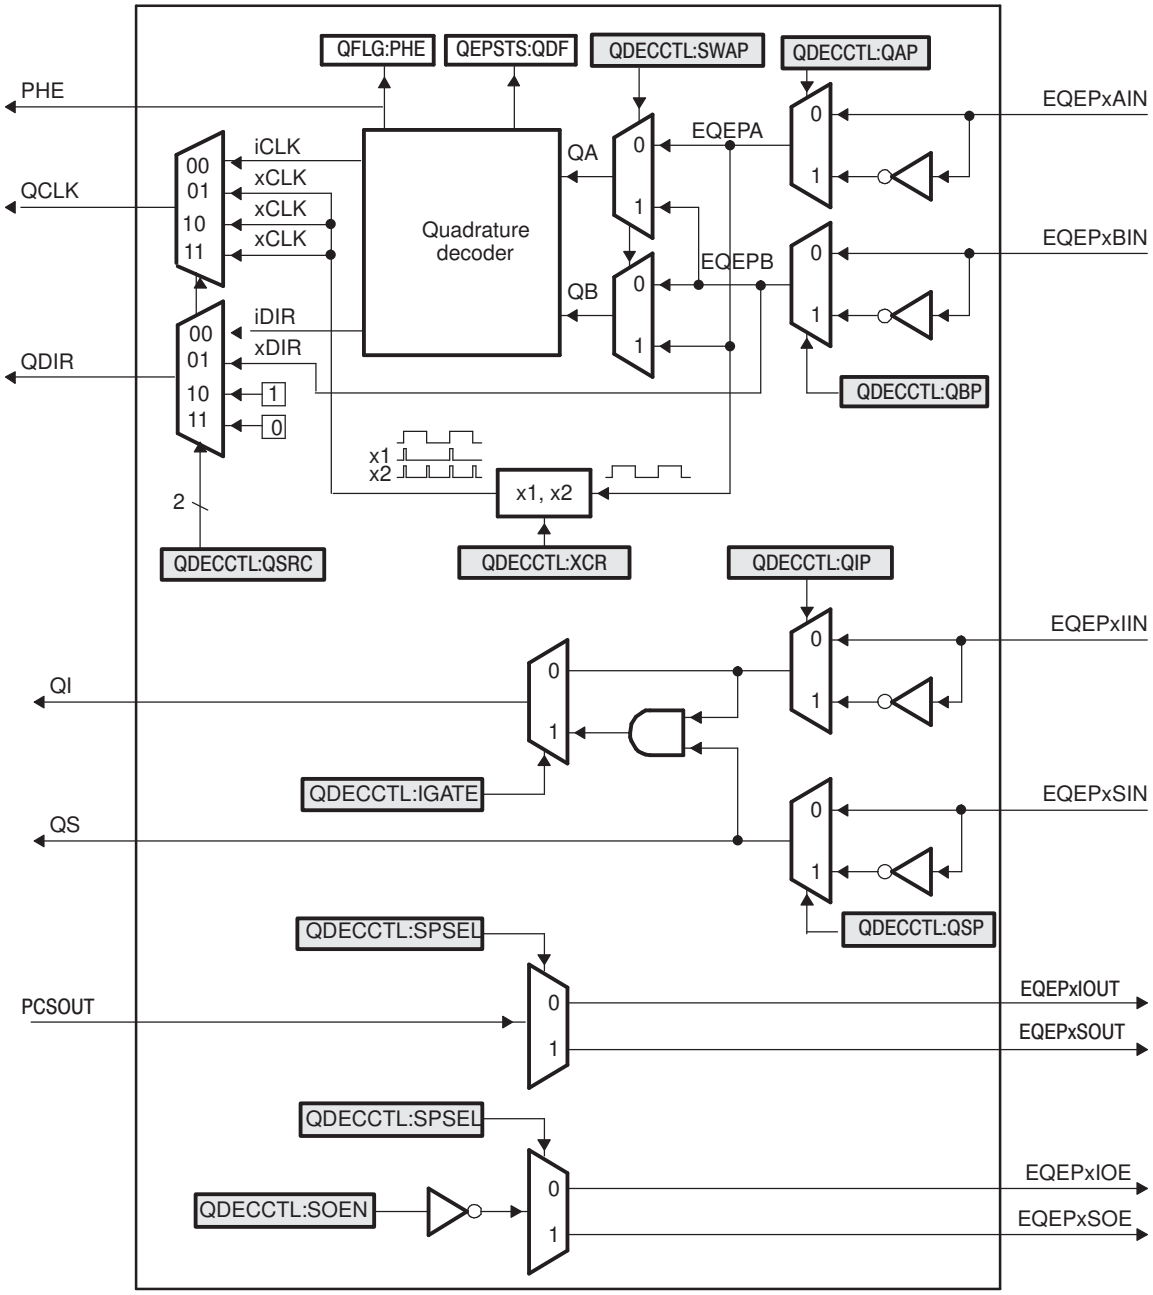
27.4 Quadrature Decoder Unit (QDU)

Figure 27-6 shows a functional block diagram of the QDU.

Figure 27-6. Functional Block Diagram of Decoder Unit



27.4.1 Position Counter Input Modes

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

27.4.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. Table 27-3 and Figure 27-7 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 27-8 shows the direction decoding and clock generation from the eQEP input signals.

Table 27-3. Quadrature Decoder Truth Table

	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

Figure 27-7. Quadrature Decoder State Machine

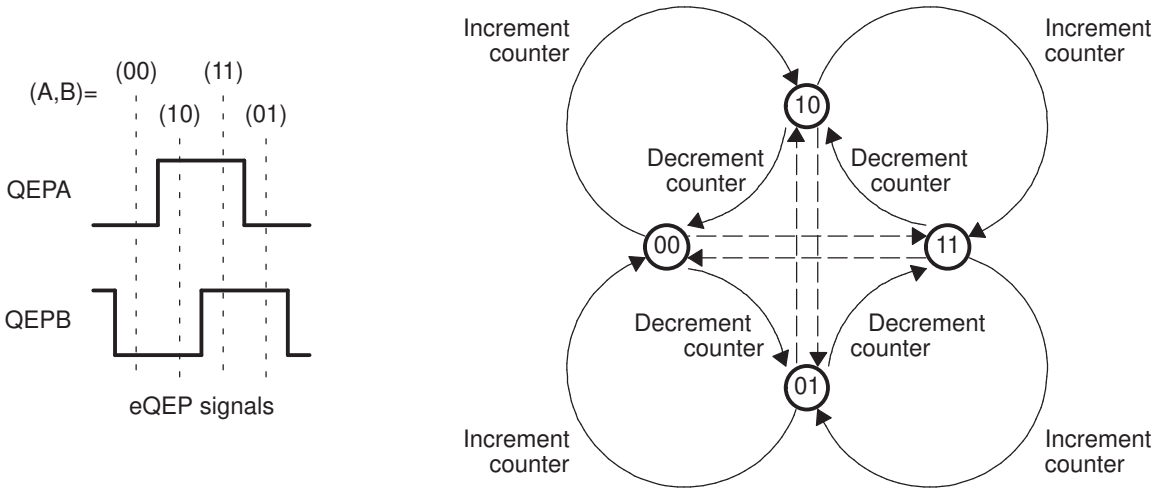

Figure 27-8. Quadrature-clock and Direction Decoding

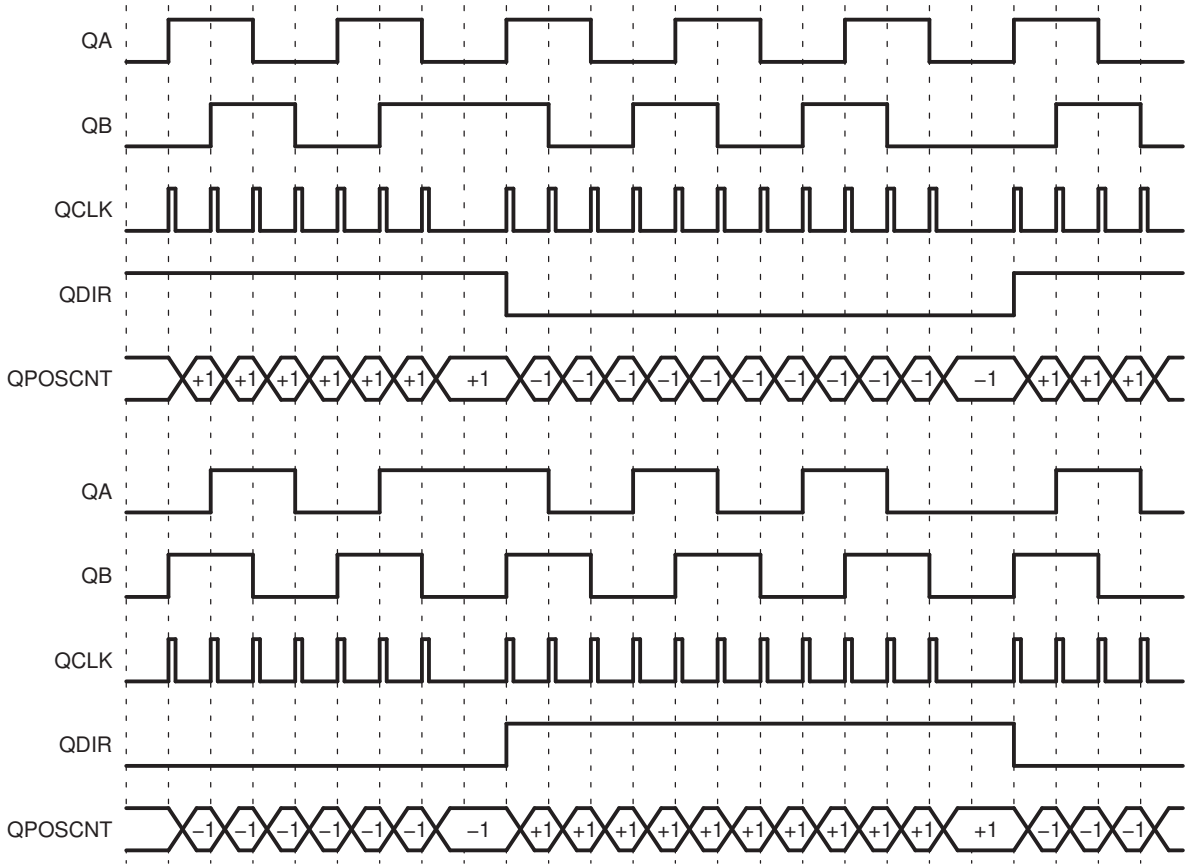


Phase Error Flag— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOSCNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 27-7 are invalid transitions that generate a phase error.

Count Multiplication— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in Figure 27-8 .

Reverse Count— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder, thereby reversing the counting direction.

27.4.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for the position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

27.4.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by a factor of 2x. In up-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

27.4.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Setting the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, it is recommended that the application not configure QEPB as a GPIO mux option, or ensure that a signal edge is not generated on the QEPB input.

27.4.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit will invert the index input.

27.4.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position- compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

27.5 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

27.5.1 Position Counter Operating Modes

Position-counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after "0". The Interrupt flag is set to indicate overflow/underflow in QFLG register.

27.5.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM]=00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.

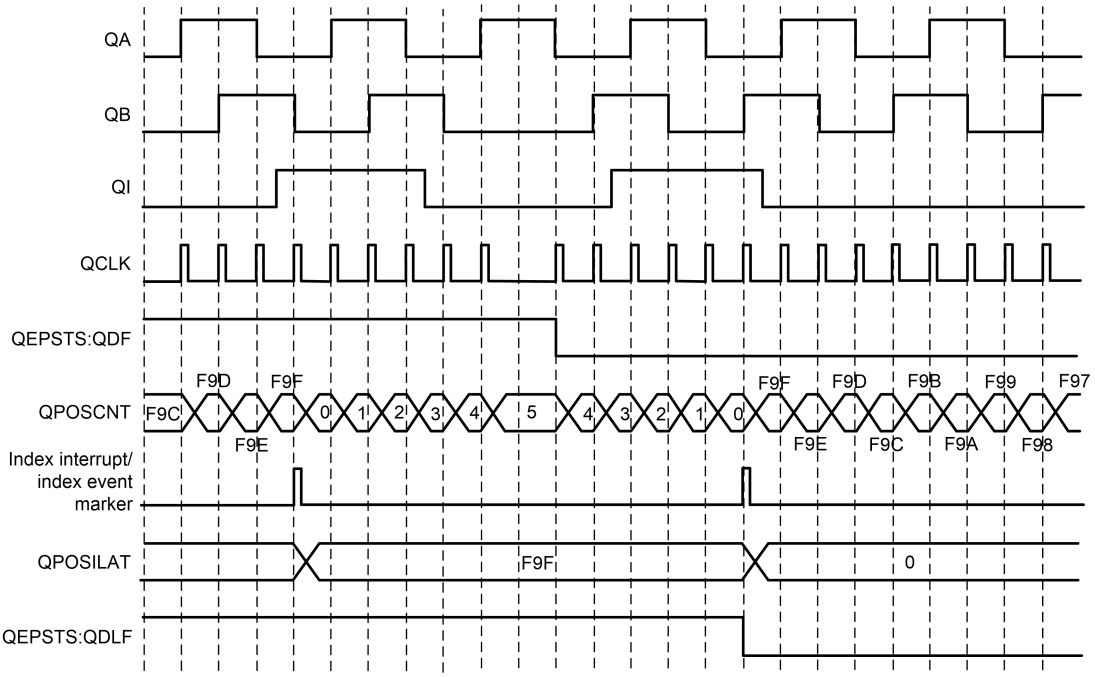
First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 27-9.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to '00' or '11' when pcrm=0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOSLAT register on every index marker.

Figure 27-9. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or 0xF9F)



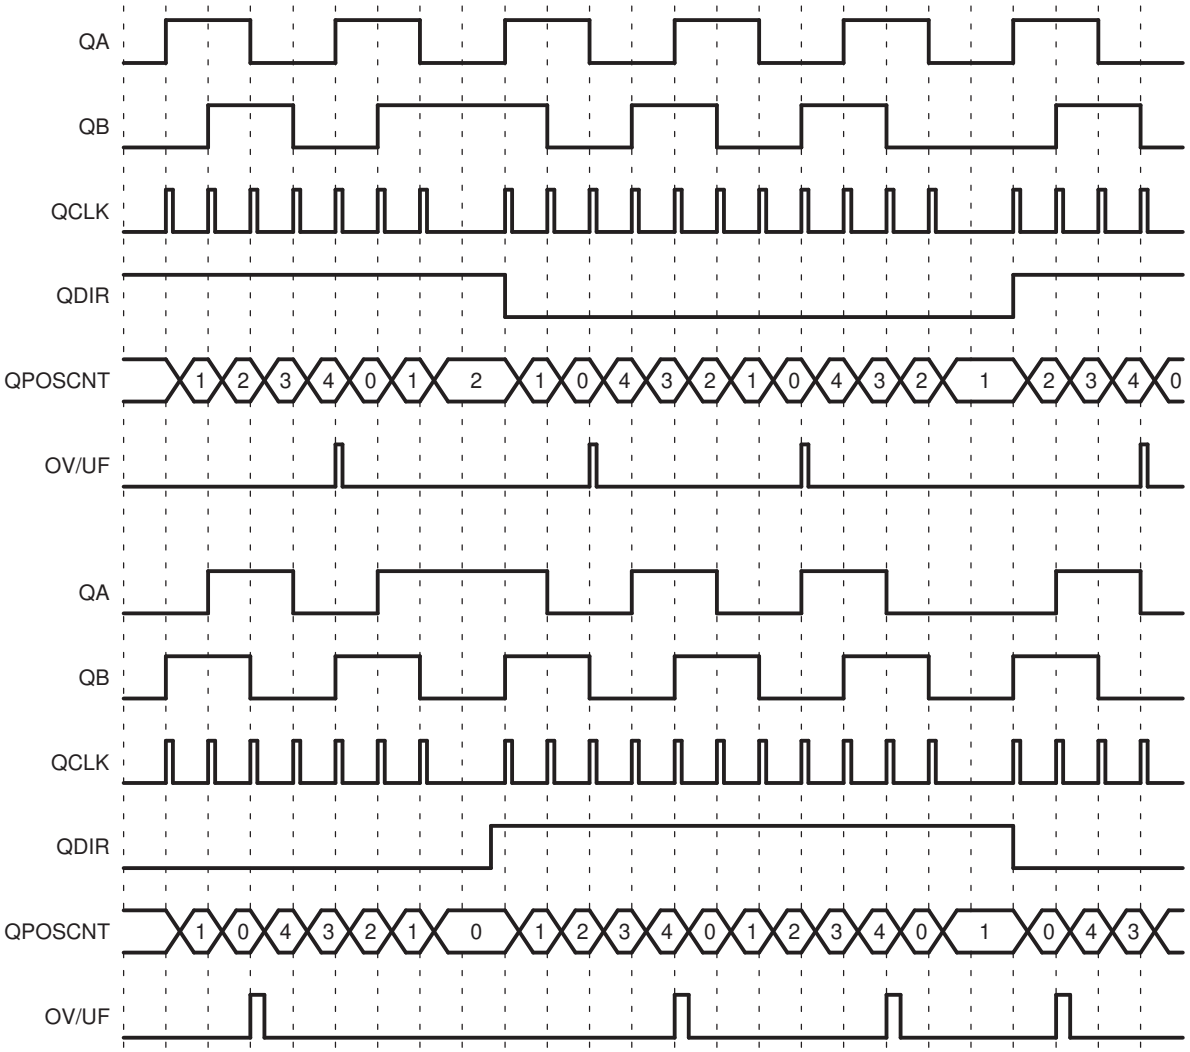
NOTE: In case of boundary condition where time period between Index Event and previous QCLK edge is less than SYSCLK period, then QPOSCNT gets reset to zero or QPOSMAX in the same SYSCLK cycle and does not wait for next QCLK edge to occur.

27.5.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 27-10 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

Figure 27-10. Position Counter Underflow/Overflow (QPOSMAX = 4)



27.5.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 27.5.1.2.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

27.5.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, QPOSCNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

27.5.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

27.5.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

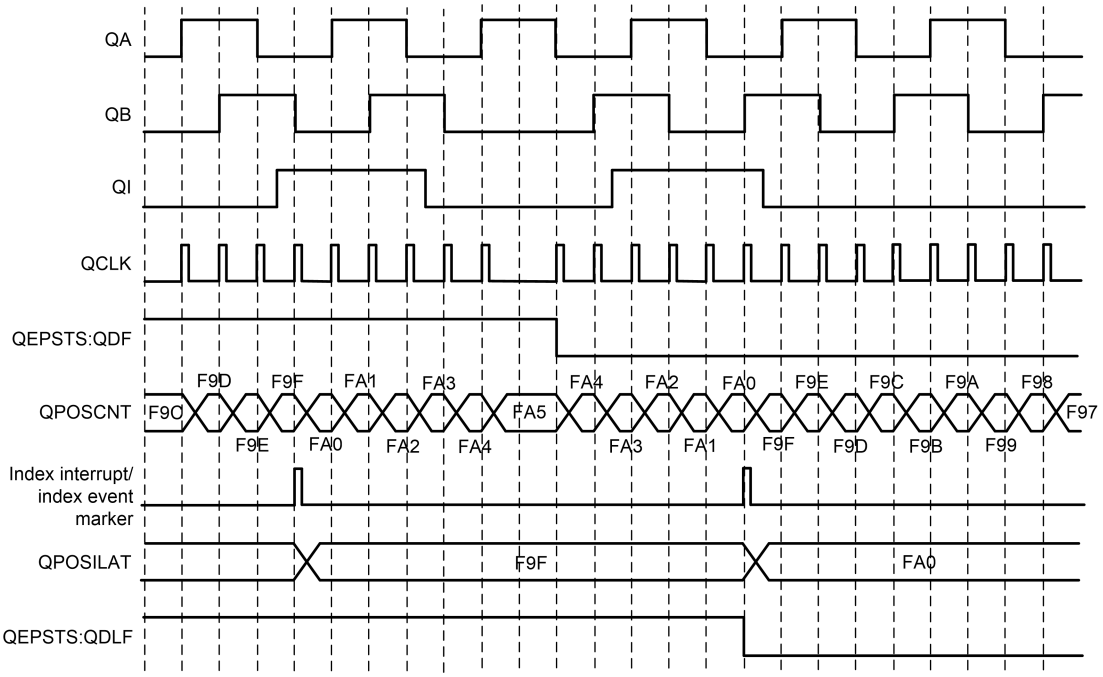
Latch on Rising Edge (QEPCTL[IEL]=01)— The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge (QEPCTL[IEL] = 10)— The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

Figure 27-11 shows the position counter latch using an index event marker.

Figure 27-11. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)



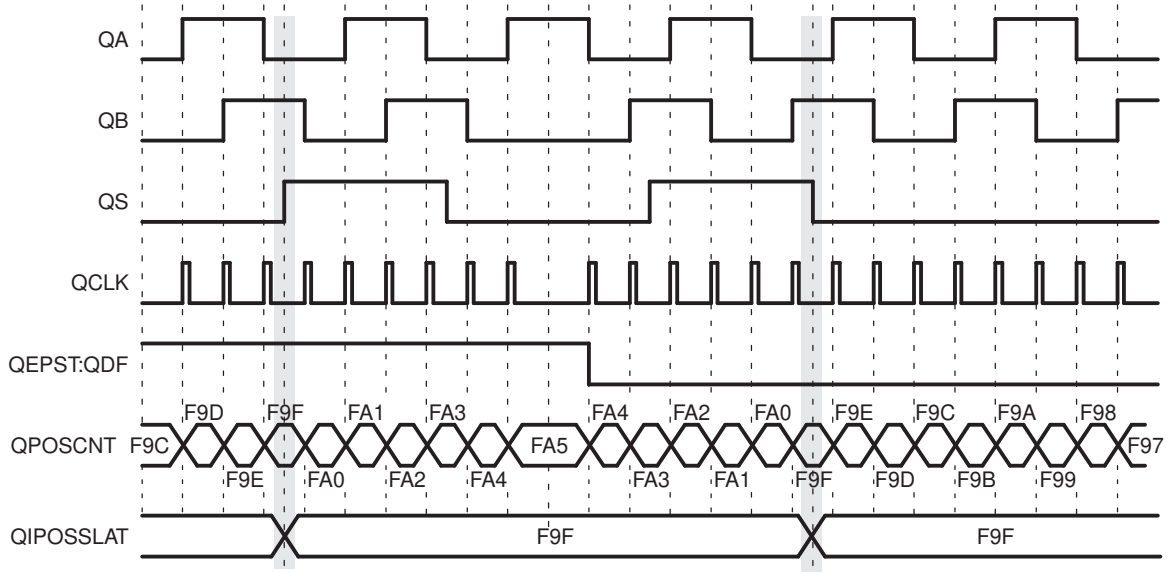
27.5.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction, and on the falling edge of the strobe input for reverse direction as shown in Figure 27-12.

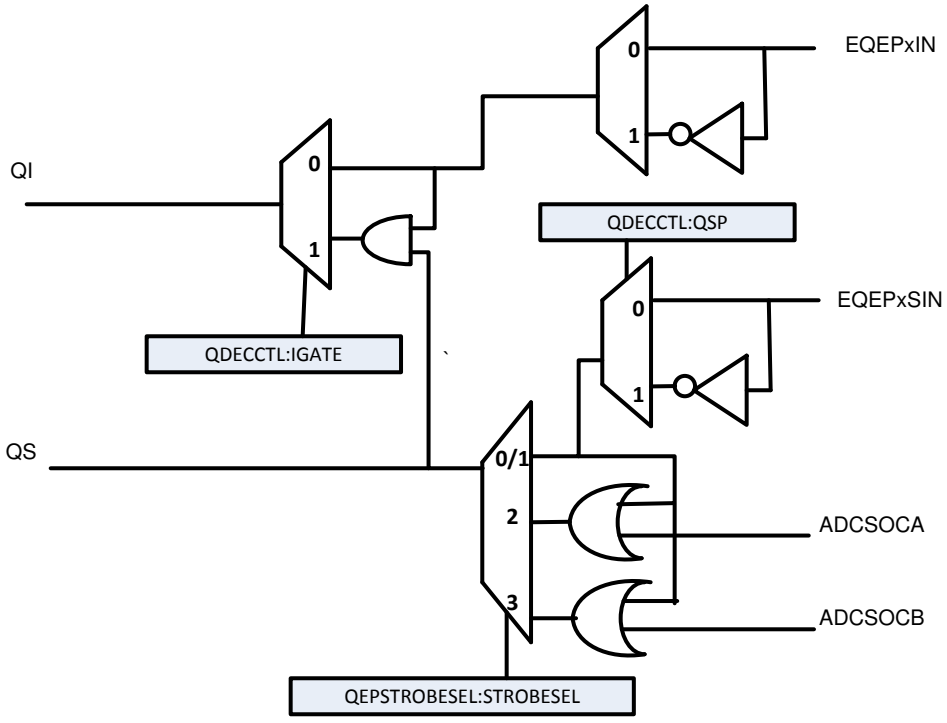
The strobe event latch interrupt flag (QFLG[SEL) is set when the position counter is latched to the QPOSSLAT register.

Figure 27-12. Strobe Event Latch (QEPCTL[SEL] = 1)



There is an added feature on Type 2.0 eQEP where position-counter value can also be latched on ADCSOCA and ADCSOSCB events by configuring the register QEPSTROBESEL.STROBESEL as shown in figure Figure 27-13

Figure 27-13. Latching Position Counter on ADCSOCA/ADCSOCB event



27.5.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization will be on the falling edge of the index input.

Strobe Event Initialization (SEI)— If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

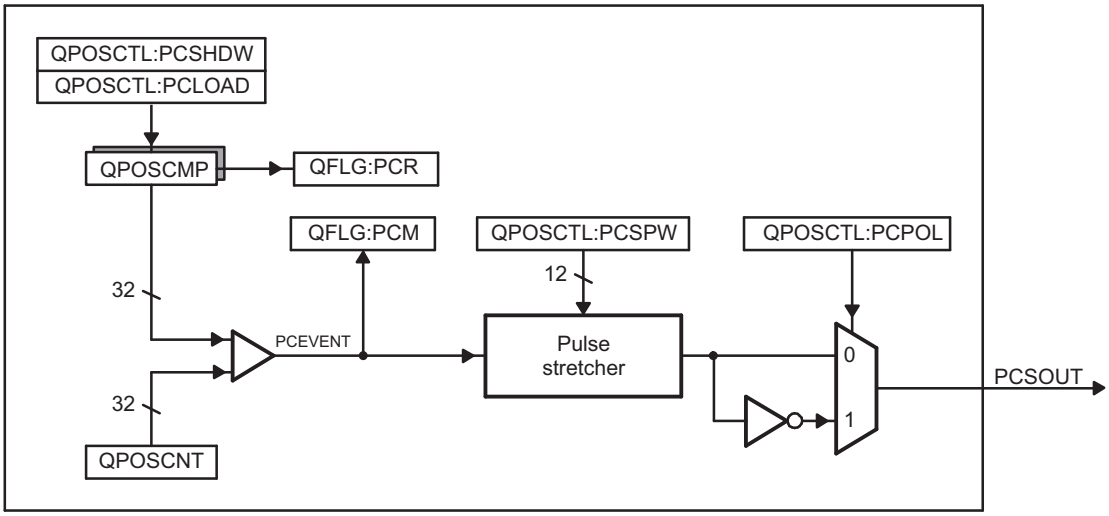
If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

Software Initialization (SWI)— The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to it again, the position counter will be re-initialized.

27.5.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 27-14 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 27-14. eQEP Position-compare Unit



In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

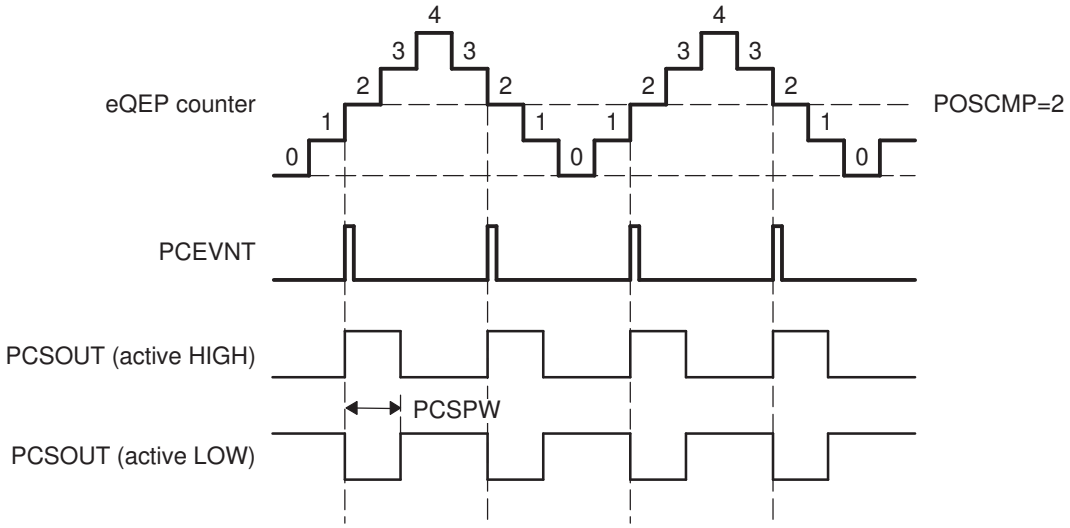
- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 27-15).

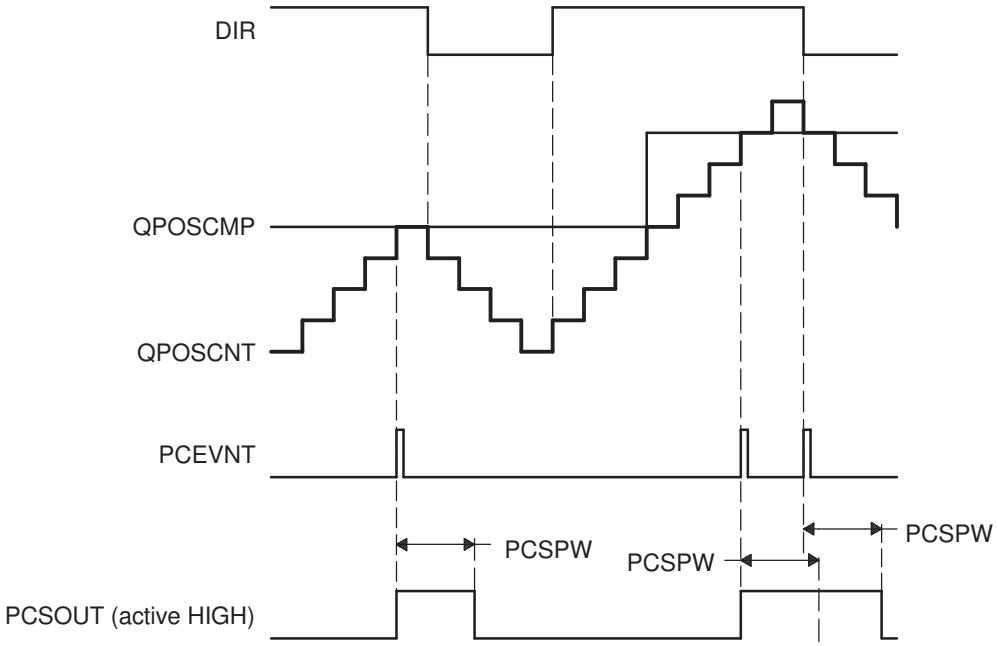
See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

Figure 27-15. eQEP Position-compare Event Generation Points



The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 27-16.

Figure 27-16. eQEP Position-compare Sync Output Pulse Stretcher



27.6 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 27-17. This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (7)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see Figure 27-18)
- ΔT - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register

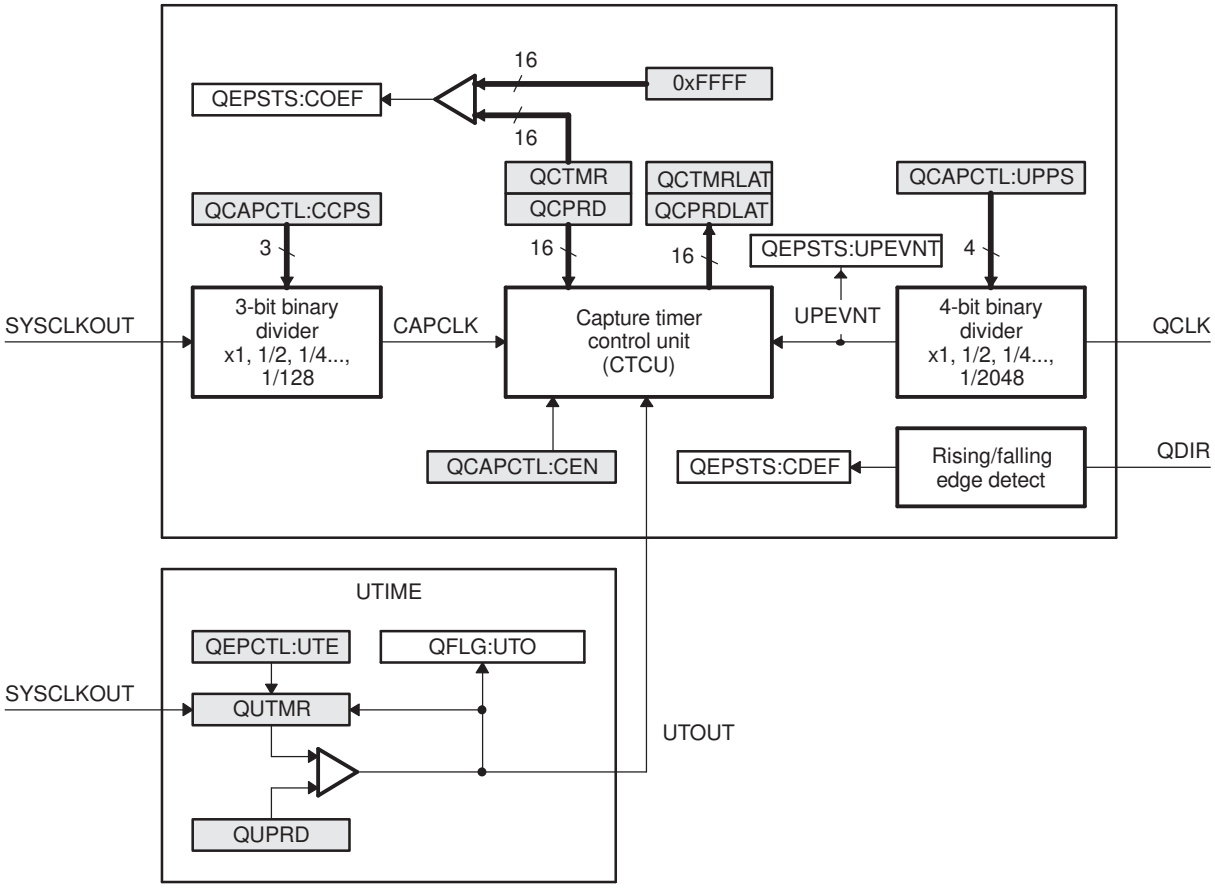
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

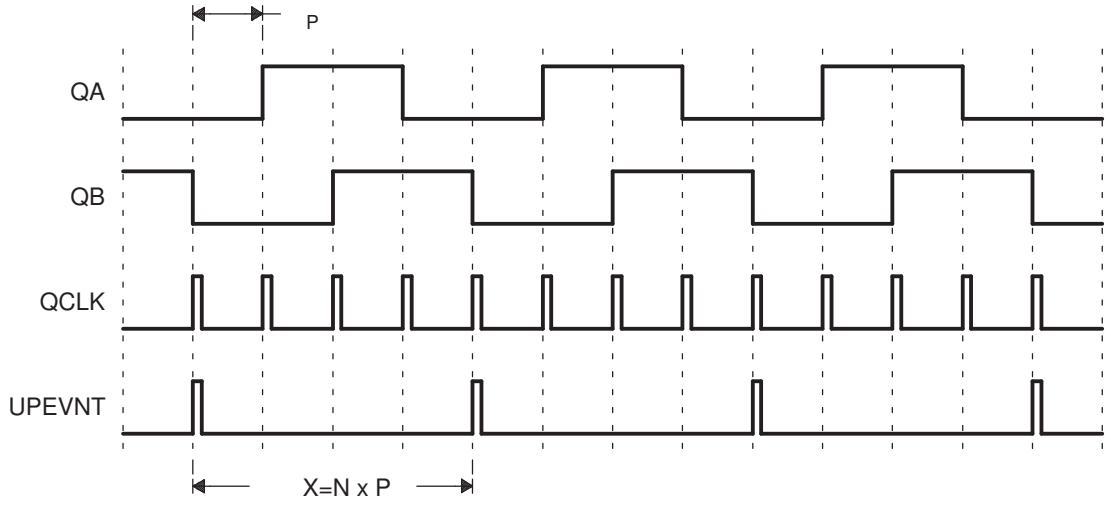
Figure 27-19 shows the capture unit operation along with the position counter.

Figure 27-17. eQEP Edge Capture Unit



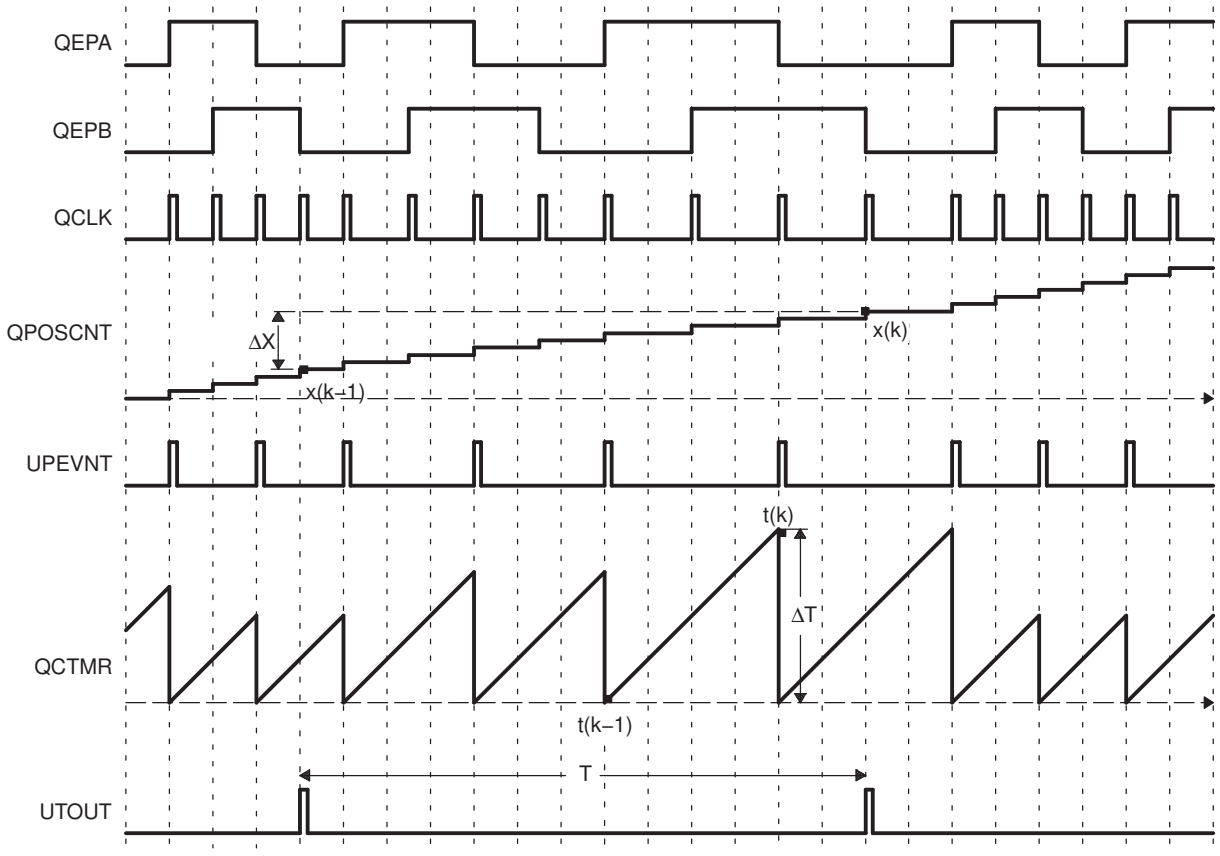
NOTE: The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CPPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

Figure 27-18. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)



A N - Number of quadrature periods selected using QCAPCTL[UPPS] bits

Figure 27-19. eQEP Edge Capture Unit - Timing Details



Velocity calculation equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (8)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k-1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

t(k-1): Time instant "k-1"

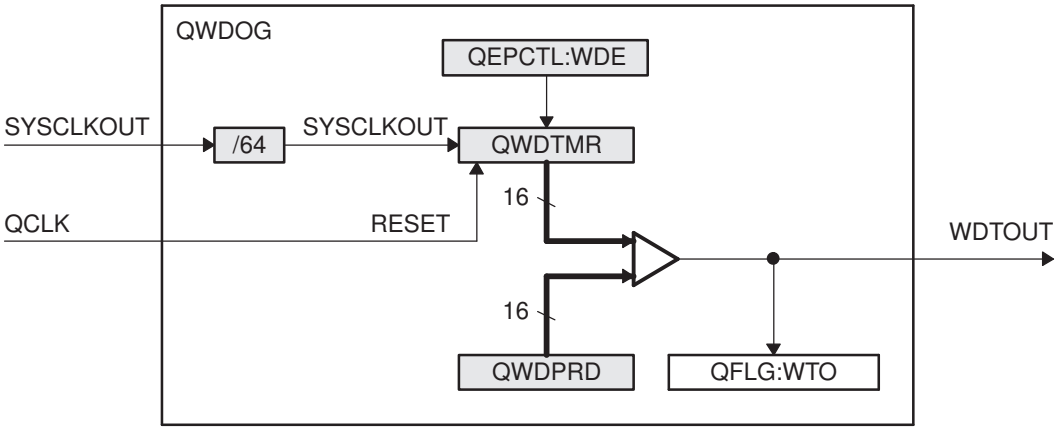
Unit time (T) and unit period(X) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (QUPRD)
ΔX	Incremental Position = QPOSLAT(k) - QPOSLAT(K-1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

27.7 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrate clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

Figure 27-20. eQEP Watchdog Timer

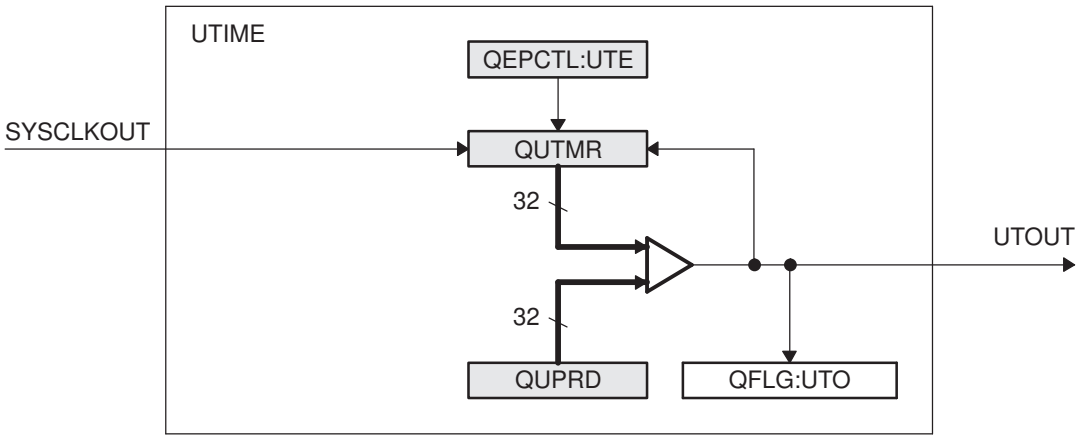


27.8 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), it resets the unit timer (QUPRD) it resets the unit timer (QUTMR) and also generates the unit time out interrupt flag (QFLG[UTO]). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 27.6.

Figure 27-21. eQEP Unit Time Base



27.9 QMA Module

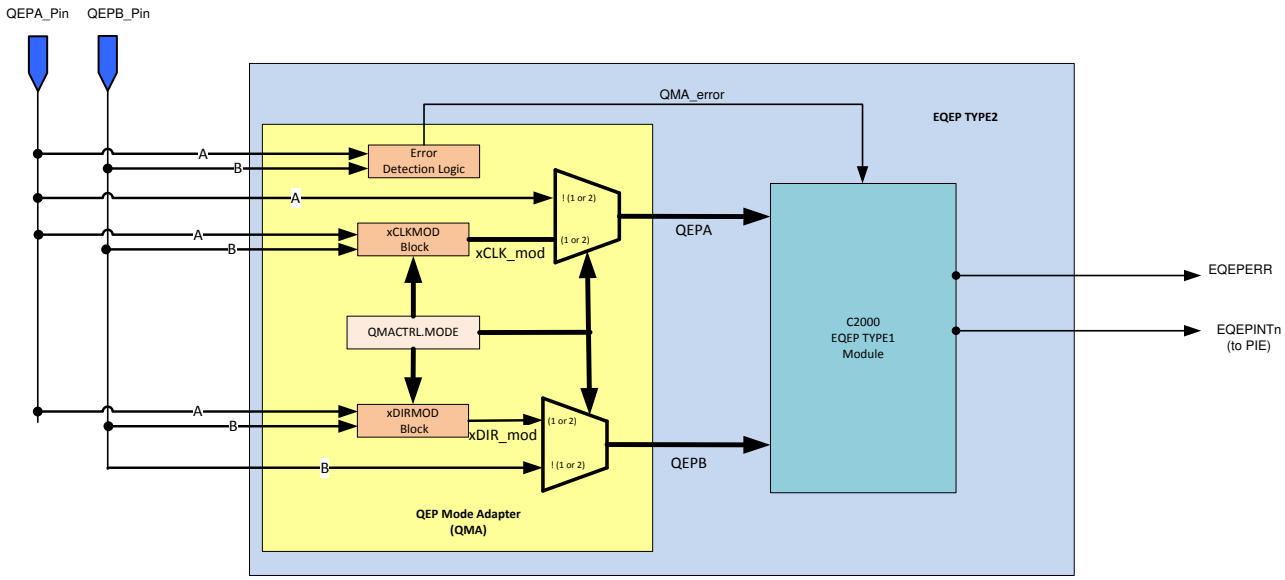
The QEP Mode Adapter (QMA) is designed to extend the C2000 eQEP module capabilities to support the additional modes described below. Figure 27-22 depicts how the QMA module is integrated into to the C2000 eQEP module.

At reset, by default QMA logic is bypassed and the EQEPA and EQEPB inputs from the pins go directly into the eQEP module. When QMA module is enabled by configuring the QMACTRL[MODE] register, the EQEPA and EQEPB input are processed by this module and modified version of EQEPA and EQEPB signals are sent to the eQEP module. The QMA module requires the eQEP module to be configured in the Direction-Count mode and generates a clock signal on EQEPA input and direction signal on EQEPB input as needed for the proper operation of the intended mode.

- The xCLKMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the clock signal on the EQEPA input to the eQEP module.
- The xDIRMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the direction signal on the EQEPB input to the eQEP module.

The QMA module has error detection logic to detect illegal transitions on EQEPA and EQEPB input signals. The QMA module's error and interrupt are integrated inside the eQEP module as described in the eQEP Interrupt Structure section. In addition QMACTRL register configuration can be locked using QMALOCK register. Refer to the register description for more details.

Figure 27-22. QMA Module Block Diagram



27.9.1 Modes of Operation

The QMA module can be operated in the following modes by configuring the QMACTRL register.

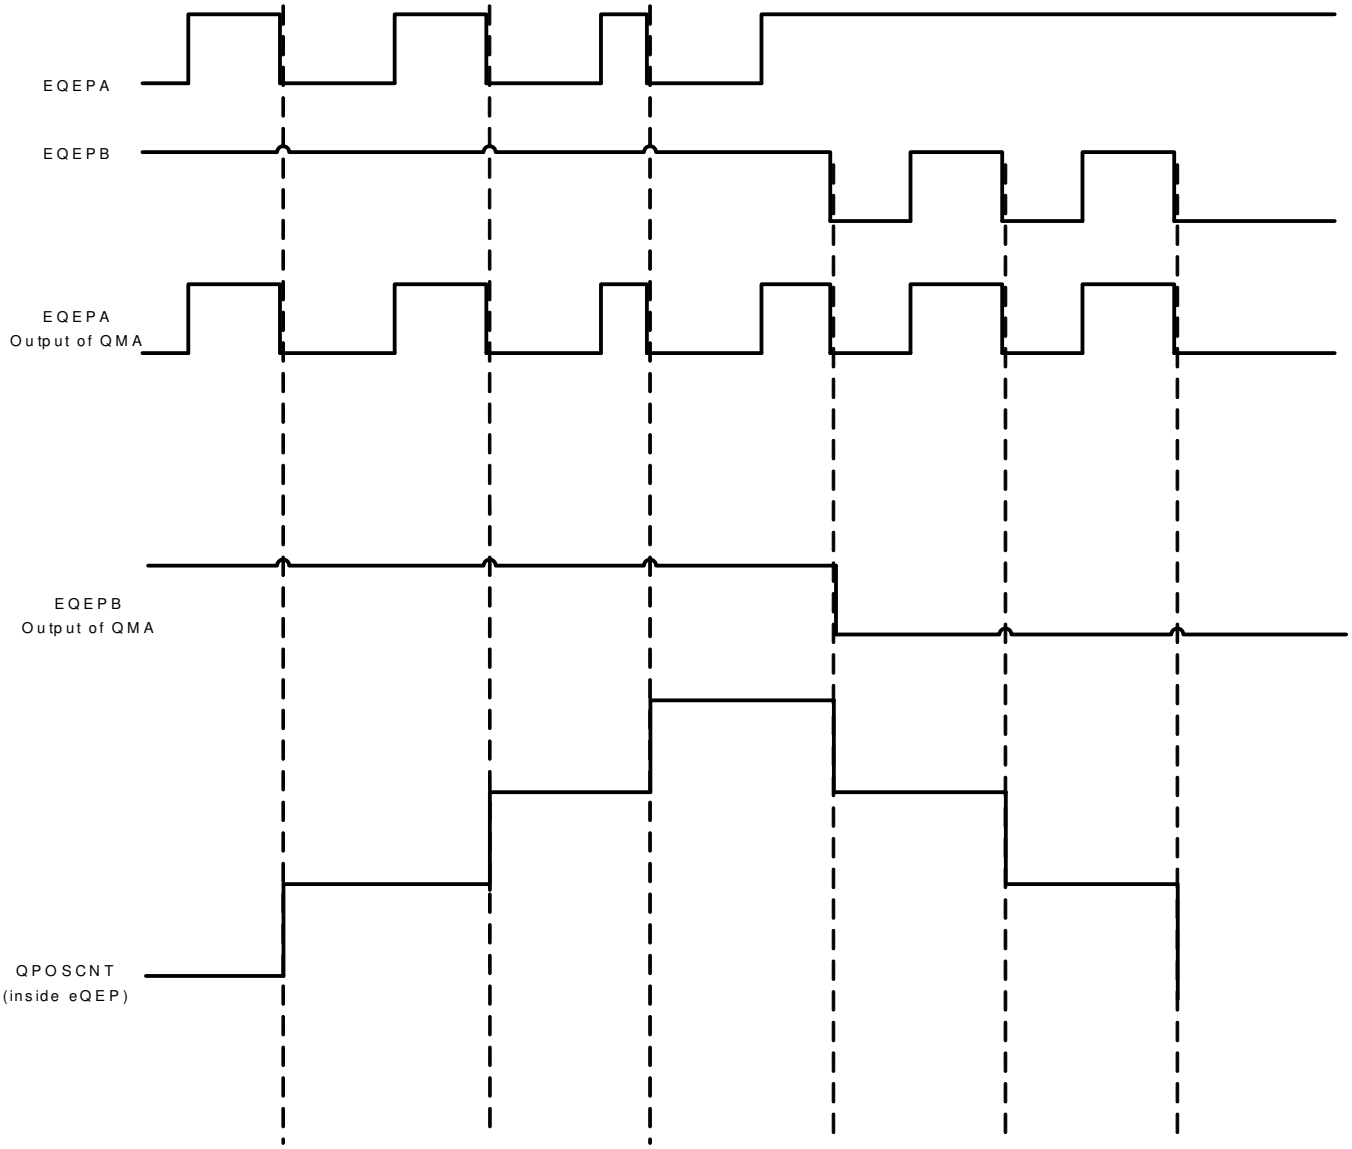
27.9.1.1 QMA Mode-1(QMACTRL[MODE]=1)

In this mode outputs of QMA correspond to the following as shown in Figure 27-23:

- EQEPA Output of QMA is AND of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is direction signal generated by QMA based on EQEPA and EQEPB inputs

This mode is used when the default state of EQEPA and EQEPB inputs is high

Figure 27-23. QMA Mode-1



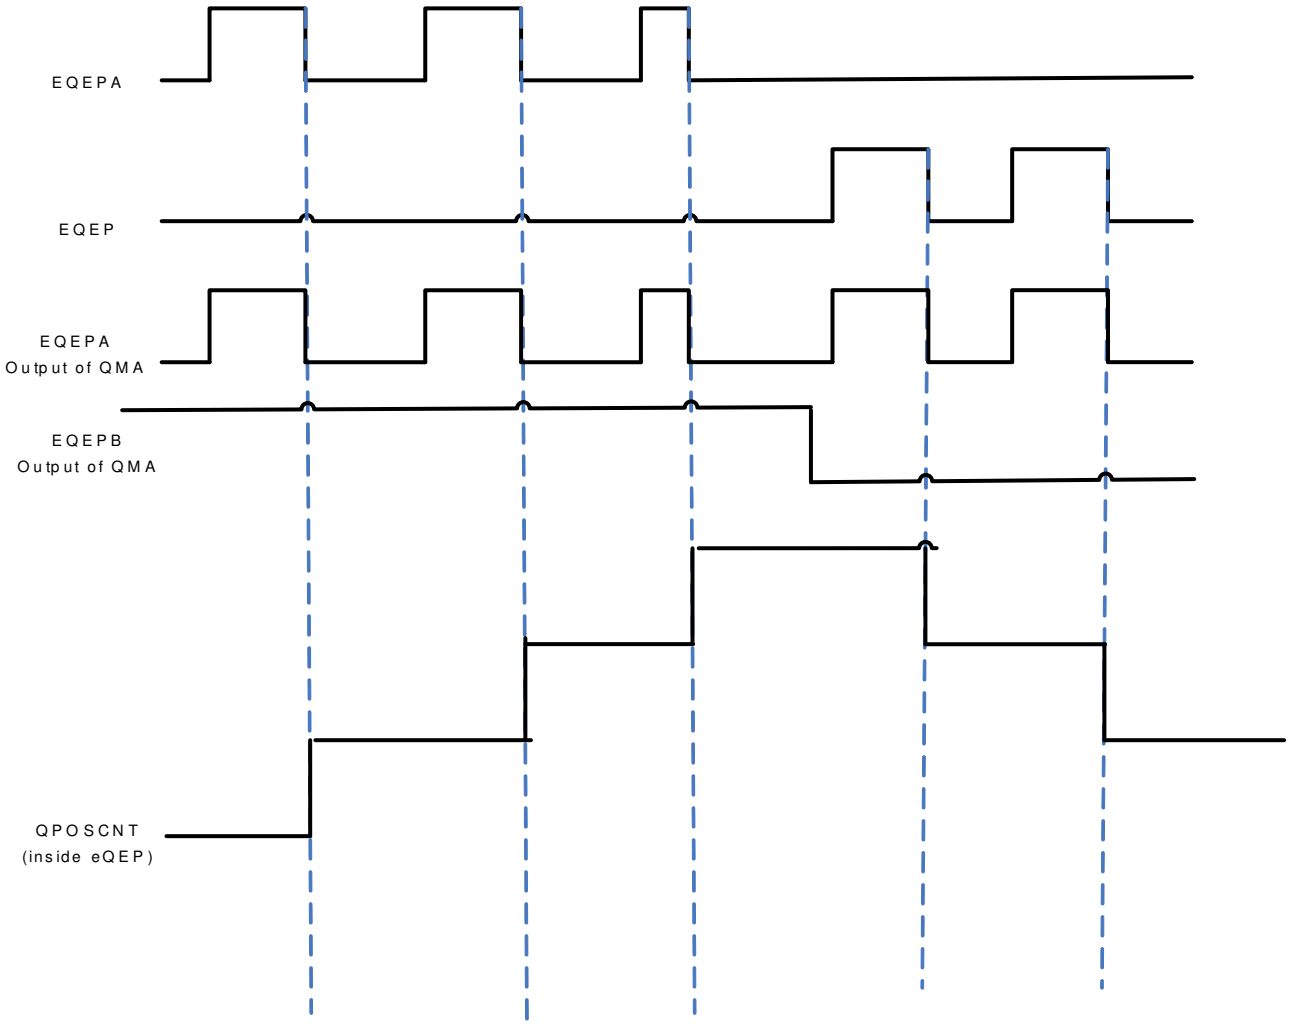
27.9.1.2 QMA Mode-2(QMACTRL[MODE]=2)

In this mode, outputs of QMA correspond to the following as shown in Figure 27-24:

- EQEPA Output of QMA is OR of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is direction signal generated by QMA based on EQEPA and EQEPB inputs

This mode is used when the default state of EQEPA and EQEPB inputs is low

Figure 27-24. QMA Mode-2



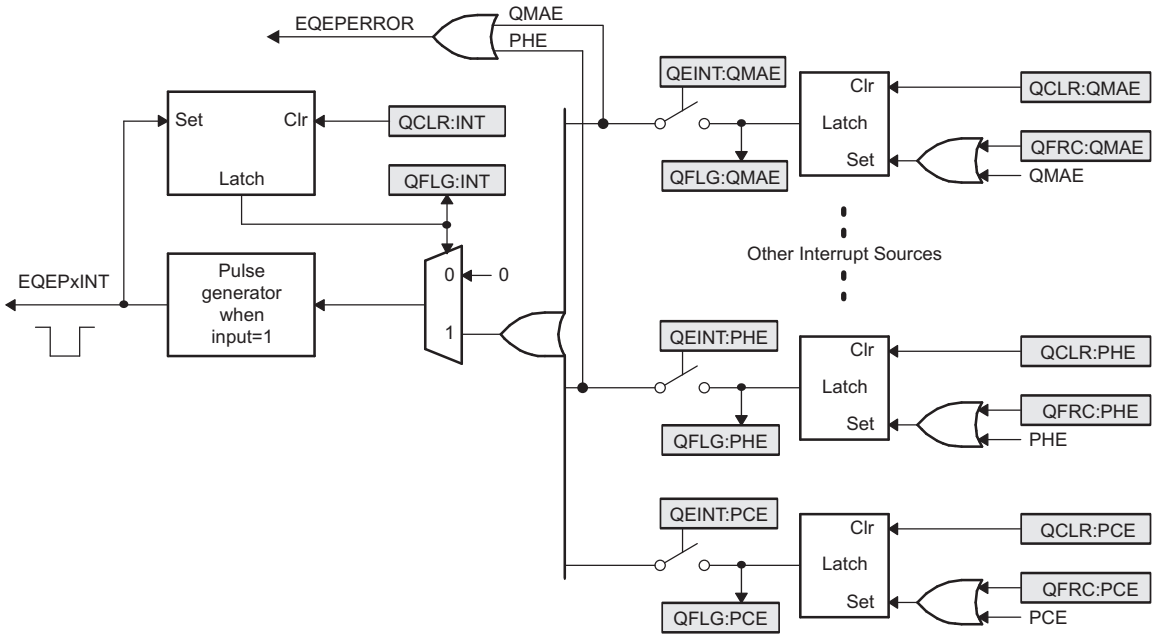
27.9.2 Interrupt and Error Generation

The error detection logic detects illegal transitions on EQEPA and EQEPB signals and generates an error signal. This error signal can be used to generate eQEP interrupt and error output. Refer to Section 27.10 for details.

27.10 eQEP Interrupt Structure

Figure 27-25 shows how the interrupt mechanism works in the EQEP module.

Figure 27-25. EQEP Interrupt Generation



Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT).

An Interrupt pulse is generated to PIE when:

a. Interrupt is enabled for eQEP event inside QEINT register

b. Interrupt flag for eQEP event inside QFLG register is set, and

c. Global interrupt status flag bit QFLG[INT] had been cleared for previously generated interrupt event. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (QCLR), before any other interrupt pulses are generated.If either flags inside the QFLG register are not cleared, further interrupt event will not generate interrupt to PIE. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

27.11 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

27.11.1 eQEP Base Addresses

Table 27-4. EQEP Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
EQep1Regs	EQEP_REGS	EQEP1_BASE	0x0000_5100	YES	YES	YES	YES	YES
EQep2Regs	EQEP_REGS	EQEP2_BASE	0x0000_5140	YES	YES	YES	YES	YES
EQep3Regs	ECAP_REGS	EQEP3_BASE	0x0000_5180	YES	YES	YES	YES	YES

27.11.2 EQEP_REGS Registers

Table 27-5 lists the EQEP_REGS registers. All register offset addresses not listed in Table 27-5 should be considered as reserved locations and the register contents should not be modified.

Table 27-5. EQEP_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	QPOSCNT	Position Counter		Go

Complex bit access types are encoded to fit into small table cells. Table 27-6 shows the codes that are used for access types in this section.

Table 27-6. EQEP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

Table 27-6. EQEP_REGS Access Type Codes (continued)

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

27.11.2.1 QPOSCNT Register (Offset = 0h) [reset = 0h]

QPOSCNT is shown in Figure 27-26 and described in Table 27-7.

Return to the Summary Table.

Position Counter

Figure 27-26. QPOSCNT Register

Table 27-7. QPOSCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	QPOSCNT	R/W	0h	Position Counter This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point. This Register acts as a Read ONLY register while counter is counting up/down. Note: It is recommended to only write to the position counter register (QPOSCNT) during initialization, i.e. when the eQEP position counter is disabled (QPEN bit of QEPCTL is zero). Once the position counter is enabled (QPEN bit is one), writing to the eQEP position counter register (QPOSCNT) may cause unexpected results. Reset type: SYSRSn

27.11.2.2 QPOSINIT Register (Offset = 2h) [reset = 0h]

QPOSINIT is shown in Figure 27-27 and described in Table 27-8.

Return to the Summary Table.

Position Counter Init

Figure 27-27. QPOSINIT Register

13-12	PCRM	R/W	0h	Postion counter reset Reset type: SYSRSn 0h (R/W) = Position counter reset on an index event 1h (R/W) = Position counter reset on the maximum position 2h (R/W) = Position counter reset on the first index event 3h (R/W) = Position counter reset on a unit time event

Table 27-19. QEPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	SEI	R/W	0h	Strobe event initialization of position counter Reset type: SYSRSn 0h (R/W) = Does nothing (action disabled) 1h (R/W) = Does nothing (action disabled) 2h (R/W) = Initializes the position counter on rising edge of the QEPS signal 3h (R/W) = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe
9-8	IEI	R/W	0h	Index event init of position count Reset type: SYSRSn 0h (R/W) = Do nothing (action disabled) 1h (R/W) = Do nothing (action disabled) 2h (R/W) = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 3h (R/W) = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)
7	SWI	R/W	0h	Software init position counter Reset type: SYSRSn 0h (R/W) = Do nothing (action disabled) 1h (R/W) = Initialize position counter (QPOSCNT=QPOSINIT). This bit is not cleared automatically
6	SEL	R/W	0h	Strobe event latch of position counter Reset type: SYSRSn 0h (R/W) = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the QDECCTL register 1h (R/W) = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe
5-4	IEL	R/W	0h	Index event latch of position counter (software index marker) Reset type: SYSRSn 0h (R/W) = Reserved 1h (R/W) = Latches position counter on rising edge of the index signal 2h (R/W) = Latches position counter on falling edge of the index signal 3h (R/W) = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the QPOSILAT register and the direction flag is latched in the QEPSTS[QDLF] bit. This mode is useful for software index marking.
3	QPEN	R/W	0h	Quadrature position counter enable/software reset Reset type: SYSRSn 0h (R/W) = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. When QPEN is disabled, some flags in the QFLG register do not get reset or cleared and show the actual state of that flag. 1h (R/W) = eQEP position counter is enabled

Table 27-19. QEPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	QCLM	R/W	0h	QEP capture latch mode Reset type: SYSRSn 0h (R/W) = Latch on position counter read by CPU. Capture timer and capture period values are latched into QCTMRLAT and QCPRDLAT registers when CPU reads the QPOSCNT register. 1h (R/W) = Latch on unit time out. Position counter, capture timer and capture period values are latched into QPOSLAT, QCTMRLAT and QCPRDLAT registers on unit time out.
1	UTE	R/W	0h	QEP unit timer enable Reset type: SYSRSn 0h (R/W) = Disable eQEP unit timer 1h (R/W) = Enable unit timer
0	WDE	R/W	0h	QEP watchdog enable Reset type: SYSRSn 0h (R/W) = Disable the eQEP watchdog timer 1h (R/W) = Enable the eQEP watchdog timer

27.11.2.14 QCAPCTL Register (Offset = 16h) [reset = 0h]

QCAPCTL is shown in Figure 27-39 and described in Table 27-20.

Return to the Summary Table.

Sigma Delta Filter Module (SDFM)

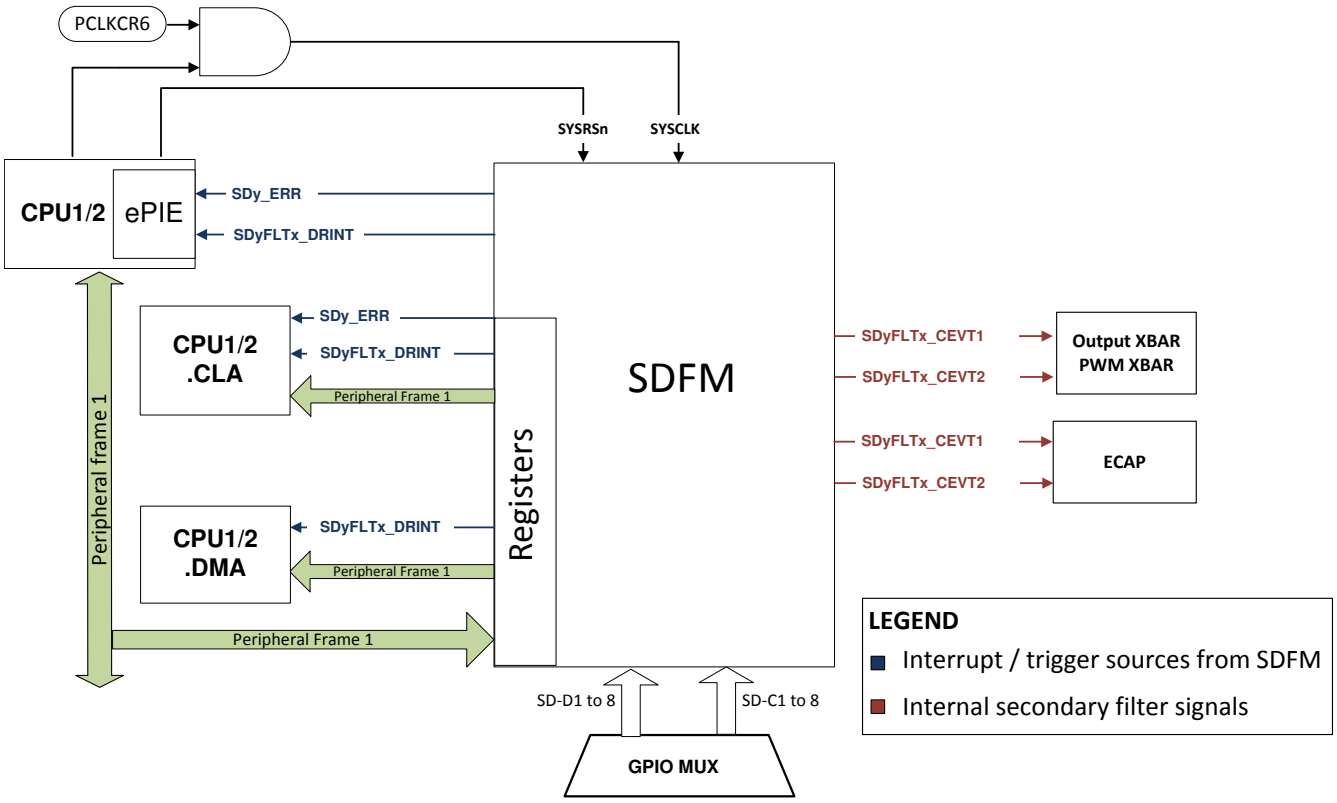
This chapter describes the sigma delta filter module (SDFM). The SDFM is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma (ΔΣ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

Topic **Page**

28.1 Introduction

Figure 28-1 shows the SDFM CPU Interface.

Figure 28-1. Sigma Delta Filter Module (SDFM) CPU Interface



28.1.1 SDFM Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Three different configurable modulator clock modes:
  - Mode 0: Modulator clock rate equals the modulator data rate.
  - Mode 1: Modulator clock rate running at half the modulator data rate.
  - Mode 3: Modulator clock rate is double that of the modulator data rate
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/Sincfast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
    1. Two independent Higher Threshold comparators (used to detect over-value condition)
    2. Two independent Lower Threshold comparators (used to detect under-value condition)
    3. One independent Threshold-Crossing comparator (used to measure duty cycle/frequency with eCAP)
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32
- Four independent configurable primary filter (data filter) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/Sincfast/Sinc3) options available
  - OSR value for data filter unit (DOSR) programmable from 1 to 256

  - Ability to enable or disable (or both) individual filter module
  - Ability to synchronize all four independent filters of an SDFM module by using the Master Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- Data filter unit has a programmable mode FIFO to reduce interrupt overhead. The FIFO has the following features:
  - The primary filter (data filter) has a 16-deep x 32-bit FIFO.
  - The FIFO can interrupt the CPU after programmable number of data-ready events.
  - FIFO Wait-for-Sync feature: Ability to ignore data-ready events until the PWM synchronization signal (SDSYNC) is received. Once the SDSYNC event is received, the FIFO is populated on every data-ready event.
  - Data filter output can be represented in either 16 bits or 32 bits.
- PWMx.SOCA/SOCB can be configured to serve as SDSYNC source on a per-data-filter-channel basis.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.
- Configurable Input Qualification available for both SD-Cx and SD-Dx
- Ability to use one filter channel clock (SD-C1) to provide clock to other filter clock channels.
- Configurable digital filter available on comparator filter events to blankout comparator events caused by spurious noise

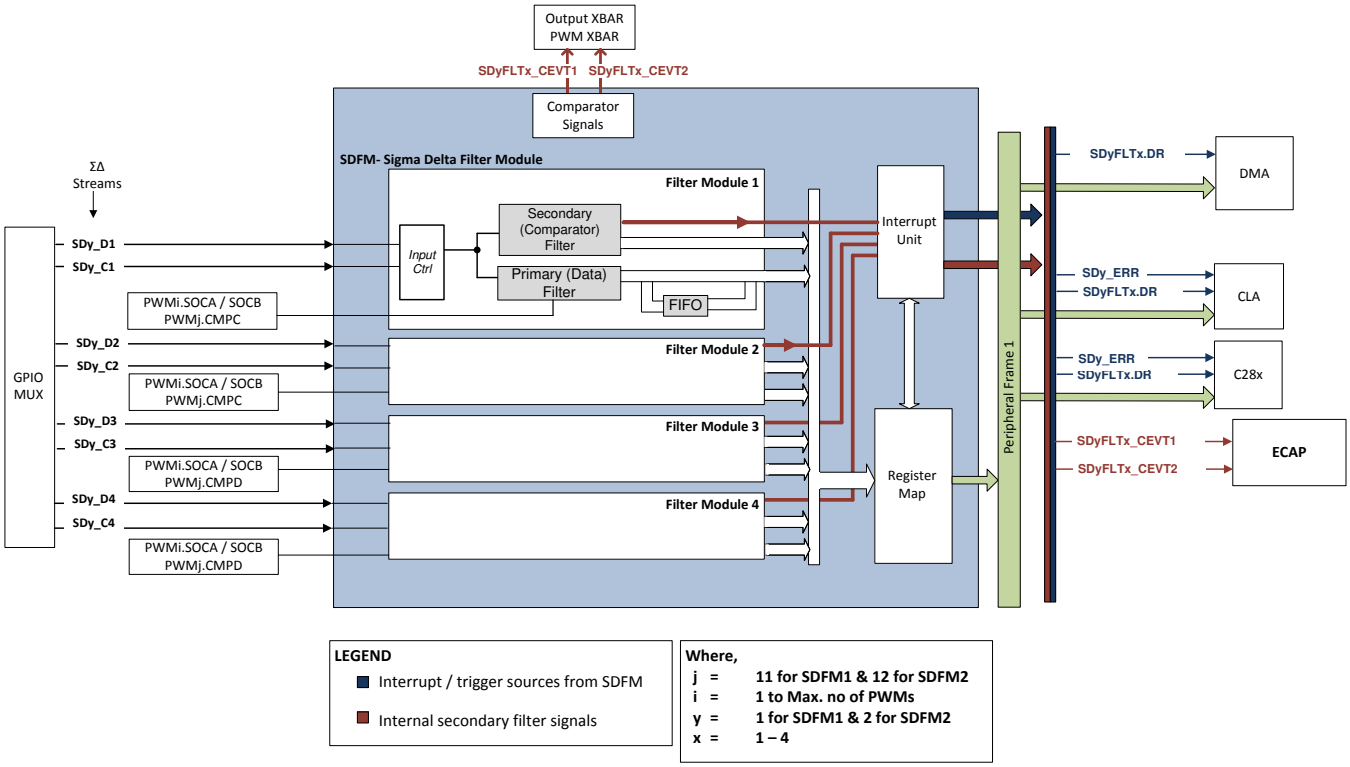
28.1.2 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

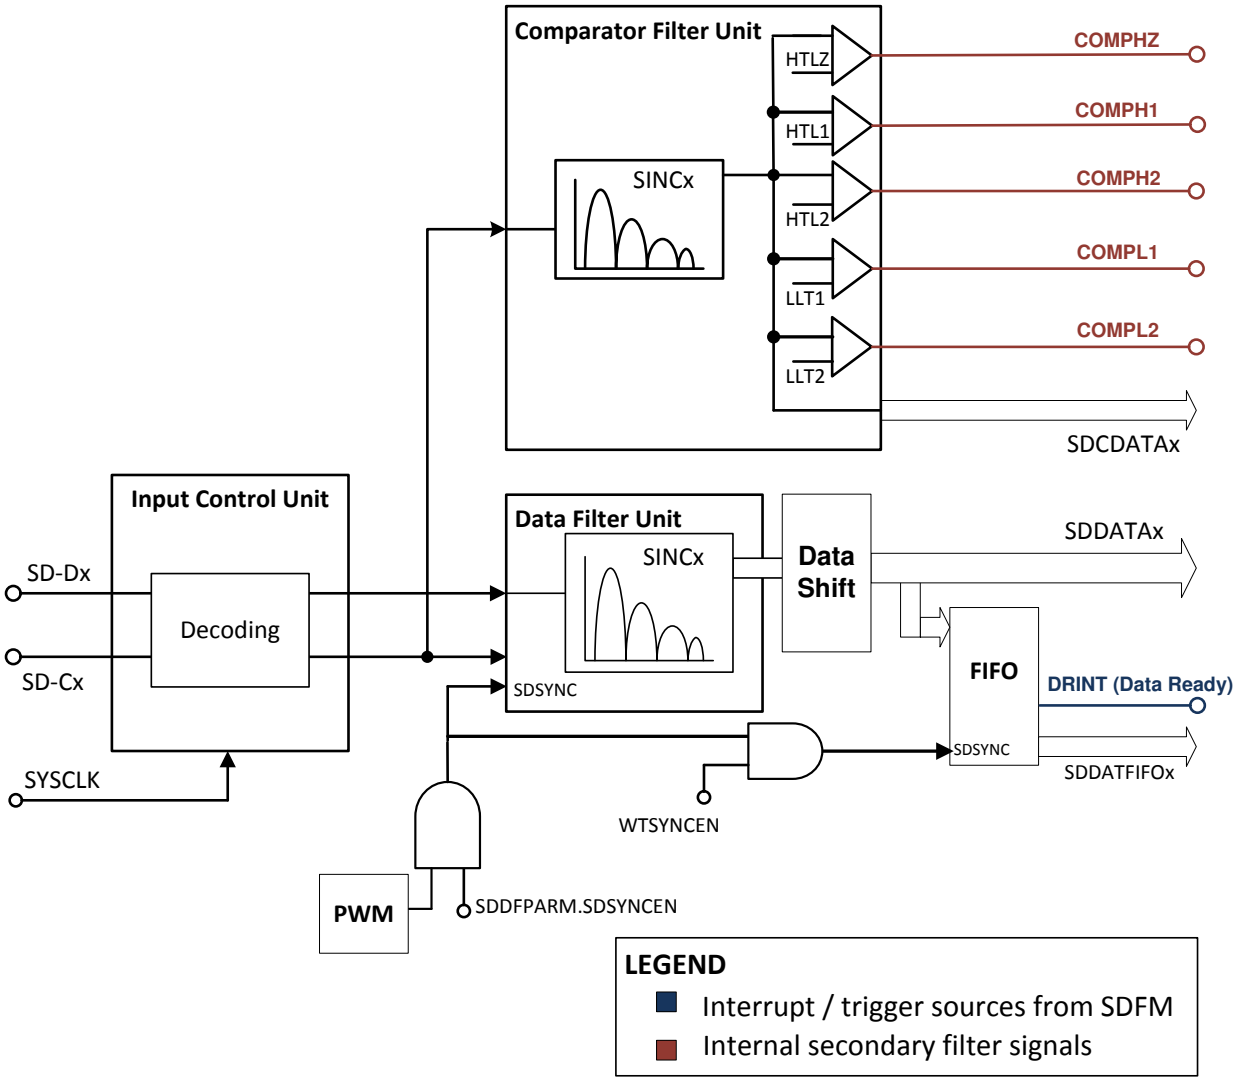
Figure 28-2 shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in .

Figure 28-2. Sigma Delta Filter Module (SDFM) Block Diagram



Each filter module shown in Figure 28-3 has a primary (data) filter and a secondary (comparator) filter pair which receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

Figure 28-3. Block Diagram of One Filter Module



28.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, following GPIO input qualification can be used. Other GPIO qualifications are not supported.

- If GPIO Input qualification is ASYNC, please make sure to check SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware of the warning message posted below.

WARNING

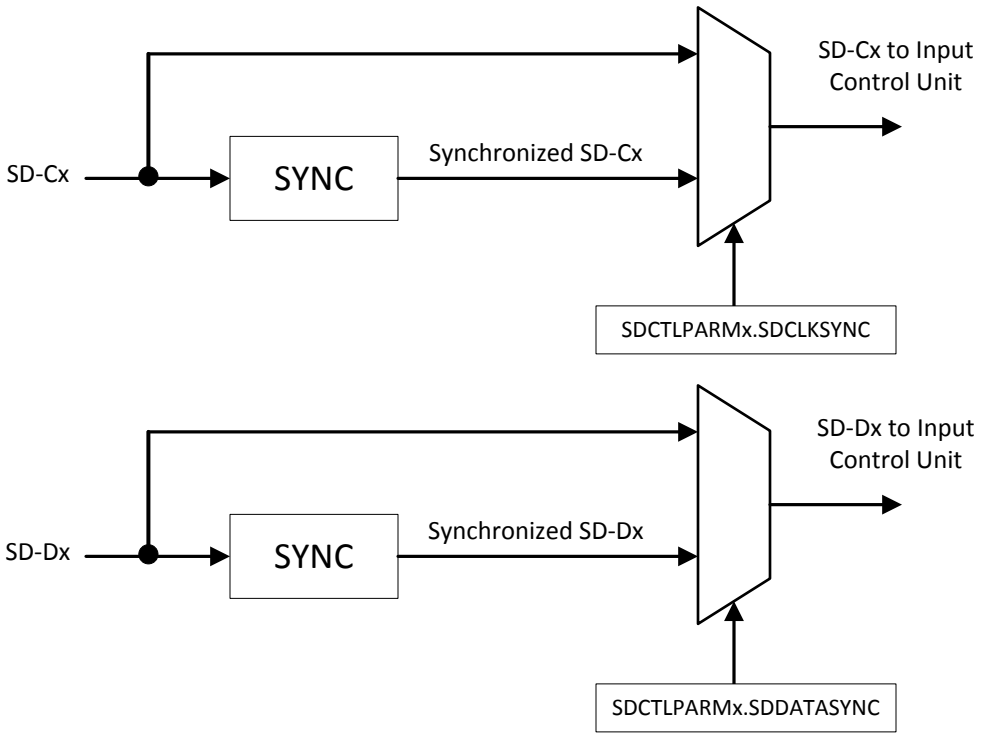
The SDFM clock inputs (SDx_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions should be taken on these signals to ensure a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

See the *GPIO* chapter for more details on GPIO mux and settings.

28.3 Input Qualification

Impulse noise sources such as EMI, crosstalk, and so on, has the possibility of corrupting SDCLK and SDDATA bit streams, resulting in corrupted SDFM filtered data. This impulse noise effects could be mitigated when using the input qualification feature which synchronizes SDCLK / SDDATA signals with PLLCLK. By default, both SDCLK and SDDATA bit stream are not synchronized. SDCLK can be synchronized to PLLCLK by setting SDCTLPARMx.SDCLKSYNC = 1 and SDDATA can be synchronized to PLLCLK by setting SDCTLPARMx.SDDATASYNC = 1.Figure 28-4 shows optional Input Qualification option on SDCLK and SDDATA lines.

Figure 28-4. Input Qualification on SD-Cx and SD-Dx



28.4 Input Control Unit

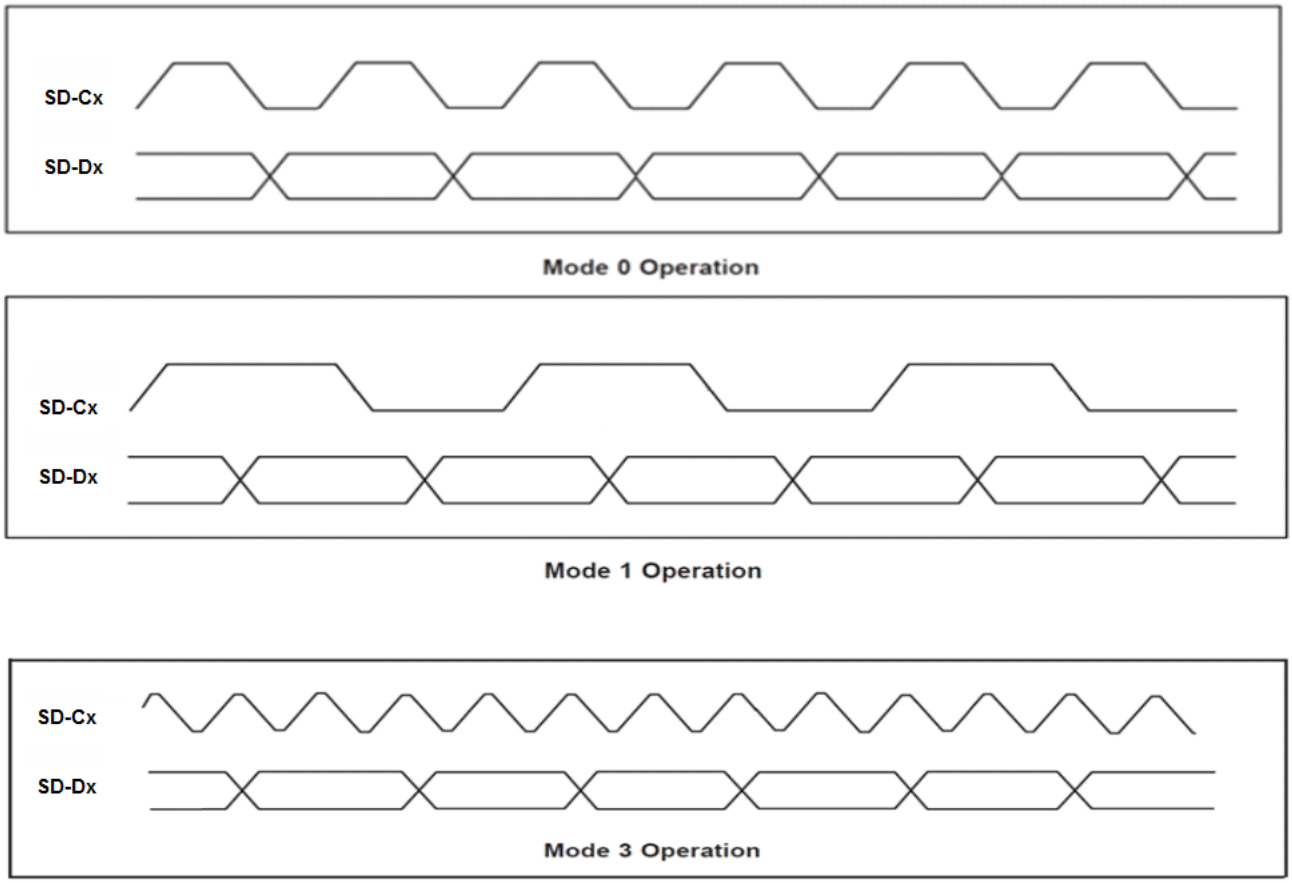
The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in four different modes. Table 28-1 and Figure 28-5 show how SDCTLPARMx.MOD bits can be configured in these four different modes.

Table 28-1. Modulator Clock Modes

MODULATOR MODE [MOD]	DESCRIPTION
0	The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock.
1	The modulator clock is running with half of the modulator data rate. The modulator data is strobed at every edge of the modulator clock.
2	Reserved
3	The modulator clock is running with double the modulator data rate. The modulator data is strobed at every other positive modulator clock edge.

NOTE: In order to achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

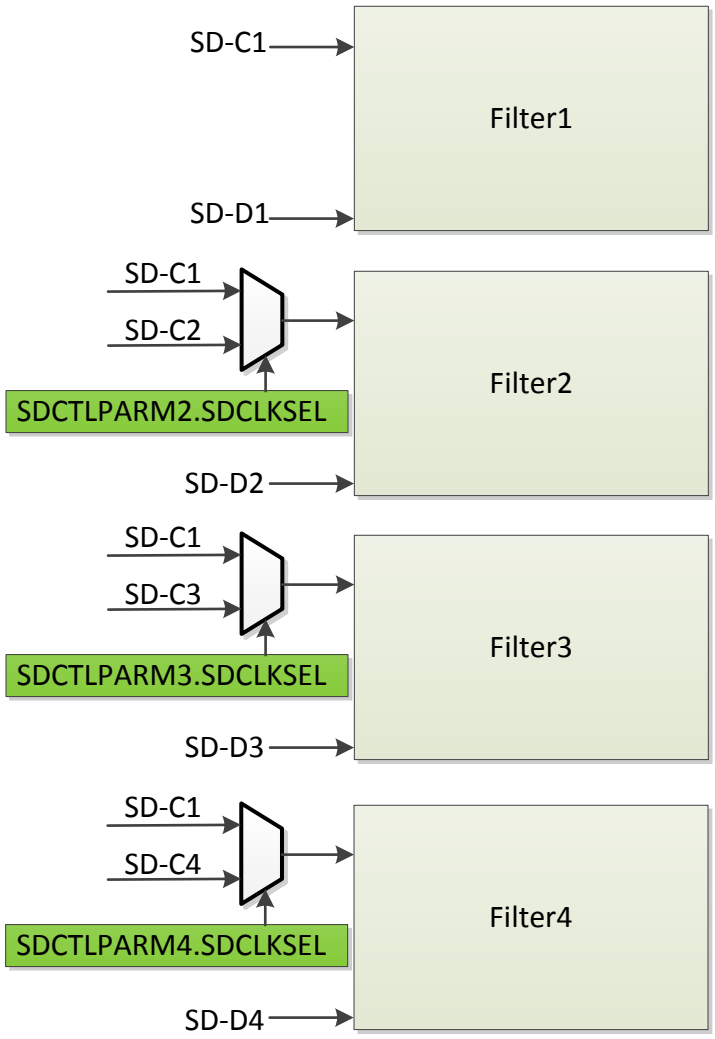
Figure 28-5. Different Modulator Modes Supported



28.5 SDFM Clock Control

In systems, the modulator clock could be generated using PWMs. Assuming all the SD-CLKs see the same delay on board traces, you could potentially use just one clock to clock multiple filters, thereby saving on the number of pins used for SDFM. In order to enable this Filter1 SDCLK (SD-C1) can possibly fed to other filter channels if required. SDCTLPARAMx.SDCLKSEL register bit field can be configured to select filter channel SDCLK. See the figure below to view this feature.

Figure 28-6. SDFM Clock Control



28.6 Sinc Filter

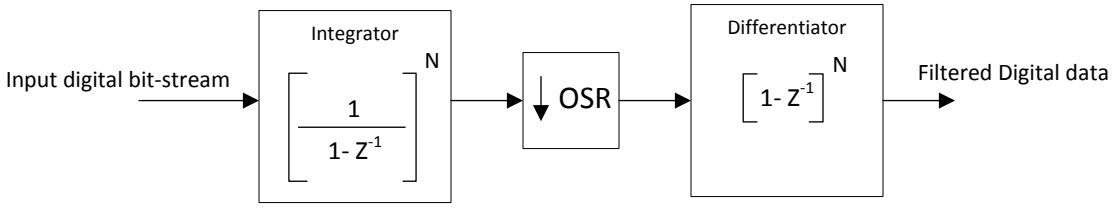
Both comparator filter and data filter available in SDFM have the Sinc^N filter as its core. The Sinc^N filter is essentially a low pass filter which converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc^N architecture consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 28-8.The Z-transfer function of the Sinc filter of order N is shown below.

Figure 28-7. Z-Transform of Sinc Filter of Order N

$$H(Z) = \left[\frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^{N}$$

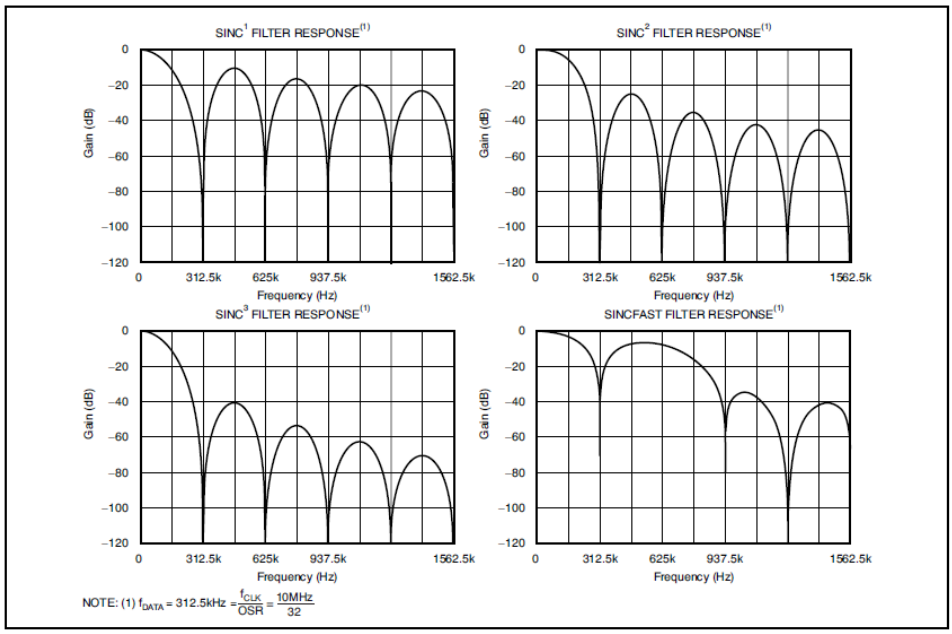
N = Order of Sinc filter
OSR = Over Sampling Ratio

Figure 28-8. Simplified Sinc Filter Architecture



Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution (or) ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator datasheet to determine the effective resolution for a given Sinc filter configuration. The figure below shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10 MHz.

Figure 28-9. Frequency Response of different Sinc Filters



The order of different sinc filter is shown in the table below.

Table 28-2. Order of Sinc Filter

filter Type	Order of Sinc Filter
Sinc1	1
Sinc2	2
Sinc3	3
SincFast	3

28.6.1 Data Rate and Latency of the Sinc Filter

The data rate of the sinc filter (filter throughput) represented in samples/sec can be calculated by the formula shown here:

$$Data\ rate\ of\ Sinc\ filter = \frac{Modulator\ data\ rate}{OSR}$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency can be calculated as shown in this equation:

$$Latency\ of\ Sinc\ filter = \frac{Order\ of\ Sinc\ filter}{Data\ rate\ of\ Sinc\ filter}$$

Example configuration:

Sinc filter type	= sinc3
Modulator data rate	= 10 MHz
OSR	= 256
Data rate of Sinc Filter	= 10 MHz / 256 = 39.1 K samples / sec
Sinc filter latency	= 76.8 µs

Sinc filter type	= sinc2
Modulator data rate	= 10 MHz
OSR	= 256
Data rate of Sinc Filter	= 10 MHz / 256 = 39.1 K samples / sec
Sinc filter latency	=51.2 µs

28.7 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3 and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDFPARMx.FEN = 1 enables the data filter. The data filter output is represented in 26-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. Table 28-3 shows the different full scale values that the data filter can store using different OSRs.

See Section 28.6.1 to understand how to calculate data rate and latency of data filter.

Table 28-3. Peak Data Values for Different DOSR/Filter Combinations

DOSR	Sinc1	Sinc2	Sinc3	Sincfast
x	x	x^2	x^3	$2x^2$
4	–4 to 4	–16 to 16	–64 to 64	–32 to 32
8	–8 to 8	–64 to 64	–512 to 512	–128 to 128
16	–16 to 16	–256 to 256	–4096 to 4096	–512 to 512
32	–32 to 32	–1024 to 1024	–32,768 to 32,768	–2048 to 2048
64	–64 to 64	–4096 to 4096	–262,144 to 262,144	–8192 to 8192
128	–128 to 128	–16,384 to 16,384	–2,097,152 to 2,097,152	–32,768 to 32,768
256	–256 to 256	–65,536 to 65,536	–16,777,216 to 16,777,216	–131,072 to 131,072

28.7.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

32-bit data filter representation:

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits

do not have any bearing on the output of the data filter in this configuration.

16-bit data filter representation:

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

  For example, for the data filter configuration below:

  – Filter type = Sinc3
  – OSR = 128
  – SDDPARMx.DR = 0

  The data filter with a 26-bit signed output value can be in the range of –16,777,216 to 16,777,216. But, 16-bit signed output supports values only from –32,768 to 32,767. Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. The table below shows the configuration settings of shift control bits for different OSR and filter types.

Table 28-4. Shift Control Bit Configuration Settings

OSR	SINC1	SINC2	SINCFAST	SINC3
1 to 31	0	0	0	0
32 to 40	0	0	0	1
41 to 50	0	0	0	2
51 to 63	0	0	0	3
64 to 80	0	0	0	4
81 to 101	0	0	0	5
102 to 127	0	0	0	6
128 to 161	0	0	1	7
162 to 181	0	0	1	8
182 to 203	0	1	2	8
204 to 255	0	1	2	9
256	0	2	3	10

WARNING

Configuring shift control bits incorrectly will result in getting incorrect 16-bit data filter output.

28.7.2 Data FIFO

Each primary (data) filter channel has a 16-level deep, 32-bit FIFO.

FIFOs can be configured to collect a programmable number of data filter samples before issuing data-ready interrupt. This reduces the number of data-ready interrupts generated and resulting interrupt overhead for managed data flow.

By default, FIFO operation is disabled. FIFOs can be enabled by setting SDFIFOCTLx.FFEN = 1. When FIFO is enabled, each data-ready event from the data filter will populate the FIFO, and the status of the FIFO at any given time is updated in the SDFIFOCTLx.SDFFST bit field.

Setting up FIFO to interrupt after receiving programmable number of data ready events:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Configure SDFIFOCTLx.SDFFIL bit field to any value between 0 to 16

- Configure SDFM data ready event to interrupt on FIFO interrupt (SDFFINT) (Set SDFFINTx = 1)
- Select data-ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

When the SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met, the SDIFLG.SDFFINTx bit is set and an interrupt is generated on the DRINTx. SDIFLG.SDFFINTx flag can be cleared by setting the SDIFLGCLR. SDFFINTx bit field.

Wait for Sync feature:

The FIFO wait for sync feature can be used to ignore data-ready events from the data filter until the SDSYNC (from PWM) event is triggered.

By default, the Wait for Sync feature is disabled. This feature can be enabled by setting SDSYNCx.WTSYNCEN = 1

When the wait for sync feature is disabled:

FIFOs get populated on every data ready event until the FIFO gets full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL.

When the wait for sync feature enabled:

FIFOs will not be get populated on every data ready event until it receives a SDSYNC event. On a SYSYNC event, it sets SDSYNCx.WTSYNFLG = 1 and data ready events from primary filter will start populating FIFO until either the FIFOs get full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL. WTSYNFLG can be cleared either automatically (or) manually.

When WTSYNFLG = 0, FIFOs contents are frozen and subsequent data ready events don't get populate FIFO until next SDSYNC event.

WTSYNFLG automatic clear mode:

By default, this mode is enabled. When SDSYNCx.WTSCLREN = 1, WTSYNFLG is automatically cleared on SDFFINT event.

WTSYNFLG manual clear mode:

Setting SDSYNCx.WTSYNCLR = 1 can be used to clear WTSYNFLG manually.

Clearing FIFO contents:

FIFO contents can cleared by any of the following methods:-

- Disabling FIFO clear FIFO contents. This can be done by clearing SDFIFOCTLx.FFEN = 0.
- Disabling Primary filter clear FIFO contents. This can done by either clearing SDDFPARMx.FEN = 0 (or) by clearing SDMFILEN.MFE = 0.
- FIFO contents can also be automatically cleared upon receiving the SDSYNC event. By default, this feature is disabled and this feature can be enabled by setting FIFO Clear-on-SDSYNC enable (SDSYNCx.FFSYNCCLREN = 1).

  Note: The above feature is only enabled when wait for sync feature is enabled (SDSYNCx. WTSYNCEN = 1).

FIFO debug access behavior:

Debug access of SDDATFIFOx registers does not affect FIFO pointers. On a CPU / CLA / DMA access to SDDATFIFOx register, FIFO read pointers would be advanced to next available entry in FIFO.

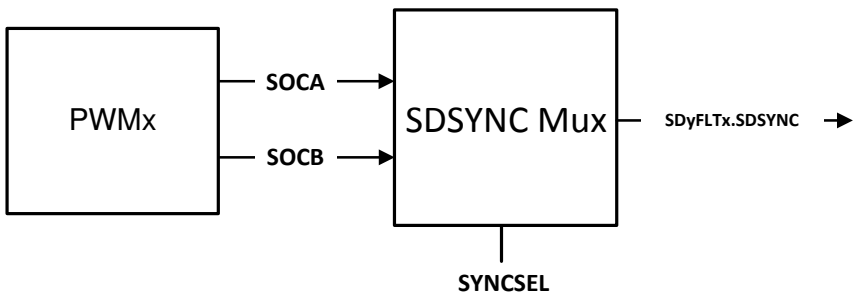
28.7.3 SDSYNC Event

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting SDDFPARMx.SDSYNCEN = 1. Each primary filter can be synchronized from any of the available PWMx. SOCA / SOCB signals. Additionally, PWM11.CMPC/CMPD can be used to reset SDFM1 filter modules and PWM12.CMPC/CMPD can be used to reset SDFM2 filter modules (see). The SDSYNCx.SDSYNCSEL bits allow the user to configure which PWM signal provides the SDSYNC pulse to the primary filter.

SDSNYx.SYNCSEL[1:0]				
SYNCSEL[5:2]	0	1	2	3
0	PWM1.SOCA	PWM1.SOCB	Rsvd	Rsvd
1	PWM2.SOCA	PWM2.SOCB	Rsvd	Rsvd
2	PWM3.SOCA	PWM3.SOCB	Rsvd	Rsvd
3	PWM4.SOCA	PWM4.SOCB	Rsvd	Rsvd
4	PWM5.SOCA	PWM5.SOCB	Rsvd	Rsvd
5	PWM6.SOCA	PWM6.SOCB	Rsvd	Rsvd
6	PWM7.SOCA	PWM7.SOCB	Rsvd	Rsvd
7	PWM8.SOCA	PWM8.SOCB	Rsvd	Rsvd
8	PWM9.SOCA	PWM9.SOCB	Rsvd	Rsvd
9	PWM10.SOCA	PWM10.SOCB	Rsvd	Rsvd
10	PWM11.SOCA	PWM11.SOCB	Rsvd	Rsvd
11	PWM12.SOCA	PWM12.SOCB	Rsvd	Rsvd
12	PWM13.SOCA	PWM13.SOCB	Rsvd	Rsvd
13	PWM14.SOCA	PWM14.SOCB	Rsvd	Rsvd
14	PWM15.SOCA	PWM15.SOCB	Rsvd	Rsvd
15	PWM16.SOCA	PWM16.SOCB	Rsvd	SDFM1.SDSYNC1 - PWM11.CMPC SDFM1.SDSYNC2 - PWM11.CMPC SDFM1.SDSYNC3 - PWM11.CMPD SDFM1.SDSYNC4 - PWM11.CMPD SDFM2.SDSYNC1 - PWM12.CMPC SDFM2.SDSYNC2 - PWM12.CMPC SDFM2.SDSYNC3 - PWM12.CMPD SDFM2.SDSYNC4 - PWM12.CMPD

Figure 28-10 shows how the PWM signals are connected to SDFM.

Figure 28-10. SDSYNC Event



NOTE: Ensure that ONLY ONE SDSYNC event will be generated per PWM timer period. Using PWM in up-count or down-count mode would automatically ensure that you get ONLY SDSYNC event. But, if up-down count mode is used, then make sure that only one SDSYNC event per PWM cycle is generated; otherwise, the filter synchronizer will corrupt SDFM timing by providing two pulses per PWM cycle.

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type will be incorrect. Table 28-5 shows the number of incorrect samples on the following conditions:-

- When Sinc filter is enabled / configured for first time.
- When Sinc filter is disabled / re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

Table 28-5. Number of Incorrect Samples Tabulated

Filter type	Number of incorrect samples after the filter is enabled and configured
Sinc1	No incorrect sample
Sinc2	The first sample of the Sinc2 filter is incorrect
SincFast	The first two samples of the SincFast filter are incorrect
Sinc3	The first two samples of the Sinc3 filter are incorrect

WARNING

SDFM comparator interrupts should be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (CEVT1 and CEVT2) should be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and five SD-Cx clock cycles.

28.8 Comparator (Secondary) Filter Unit

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

NOTE: The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

The comparator filter is a configurable Sinc filter which supports the following filter types: - Sinc1, Sinc2, Sinc3 and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is disabled and setting SDCPARMx.CEN = 1 enables the comparator filter. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as ‘0’ and a high input signal as ‘1’. The resulting calculations give only positive values for the output of the comparator filter. Table 28-6 shows the different full-scale values that the comparator filter can store using different OSRs.

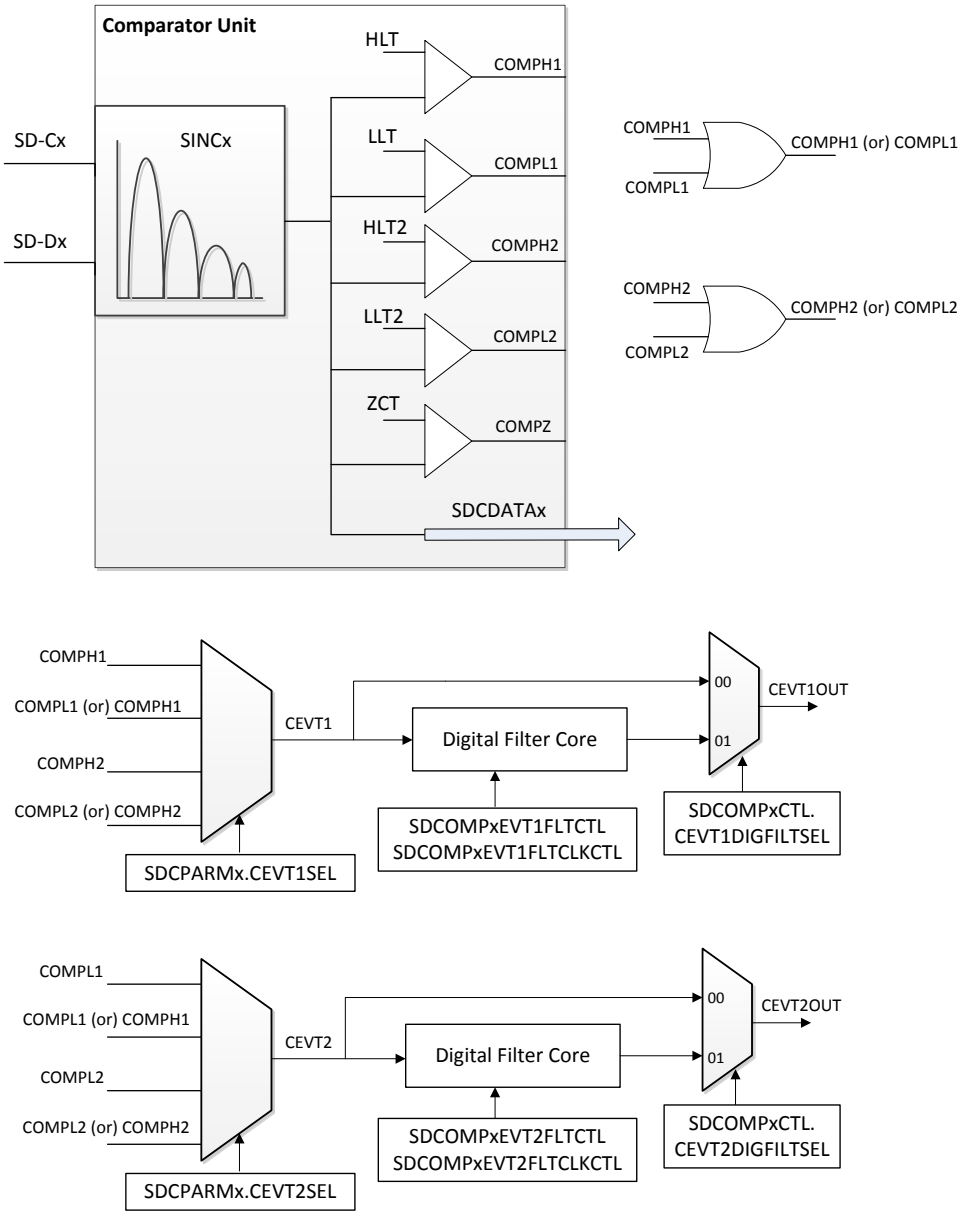
Table 28-6. Peak Data Values for Different OSR/Filter Combinations

OSR	Sinc1	Sinc2	Sinc3	Sincfast
x	0 to x	0 to x2	0 to x3	0 to 2x2
4	0 to 4	0 to 16	0 to 64	0 to 32
8	0 to 8	0 to 64	0 to 512	0 to 128
16	0 to 16	0 to 256	0 to 4096	0 to 512
32	0 to 32	0 to 1024	0 to 32,768	0 to 2048

See Section 28.6.1 to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is memory-mapped and can be read in the SDCDATAx register. This register, SDCDATAx, is updated every COSR number of SD-Cx cycles. The comparator filter digital output is connected to digital comparators explained below.

Figure 28-11. Comparator Unit Structure



28.8.1 Higher threshold (HLT) comparators

- High threshold comparator can be used to detect over-value condition.

- When comparator data > = higher threshold register, a high threshold event is generated.
- Higher threshold comparator events except for COMPHZx can be configured to trigger following events : CPU interrupt, CLA task, PWM trip.
- Higher threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of threshold crossing
- This device has three High Threshold comparators.
  - **Higher Threshold 1 (HLT1) comparator** :
    - When comparator data > = (SDFLTxCMPH1.HLT), HLT1 comparator generates COMPH1 event.
    - The COMPH1 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold 2 (HLT2) comparator**
    - When comparator data > = (SDFLTxCMPH2.HLT), HLT2 comparator generates COMPH2 event.
    - The COMPH2 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold (HTLZ) comparator**
    - When comparator data > = (SDFLT1CMPHZ.CMPHZ), it can generate a Higher Threshold (B) event (COMPHZx) and sets the corresponding SDSTATUS.HZx flag. But, this event cannot be configured to generate SDFM interrupt (SDx_ERR). The high threshold (HTLZ) comparator can be used in conjunction with eCAP to measure the frequency / duty cycle of threshold crossing events.

28.8.2 Lower Threshold (LLT) comparators

- The low threshold comparator can be used to detect under-value condition.
- When comparator data < = Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events : CPU interrupt, CLA task, PWM trip.
- Lower threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of Threshold crossing
- This device has two low threshold comparators.
  - **Lower Threshold 1 (LLT1) Comparator**
    - When omparator data < = (SDFLTxCMPL1.LLT), the LLT1 comparator generates COMPL1 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.
  - **Lower Threshold 2 (LLT2) Comparator**
    - When omparator data < = (SDFLTxCMPL2.LLT), LLT2 comparator generates COMPL2 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.

28.8.3 Digital Filter

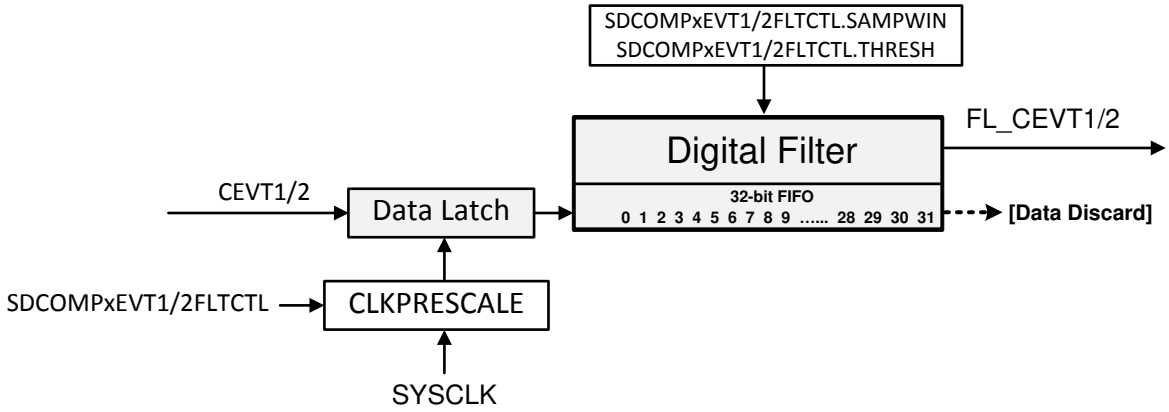
The digital filter works on a window of FIFO samples (SAMPWIN + 1) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than SAMPWIN / 2.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every CLKPRESCALE system clocks. Old data from the FIFO is discarded.

A conceptual model of the digital filter is shown in the figure below.

Figure 28-12. Digital Filter



Equivalent C code of the filter implementation is shown below:

```
if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
```

Filter Initialization Sequence

To ensure proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure the digital filter parameters for operation:
   - Set SAMPWIN for the number of samples to monitor in the FIFO window.
   - Set THRESH for the threshold required for majority qualification.
   - Set CLKPRESCALE for the digital filter clock prescale value.
2. Initialize the sample values in the digital FIFO window by setting FILINIT = 1.

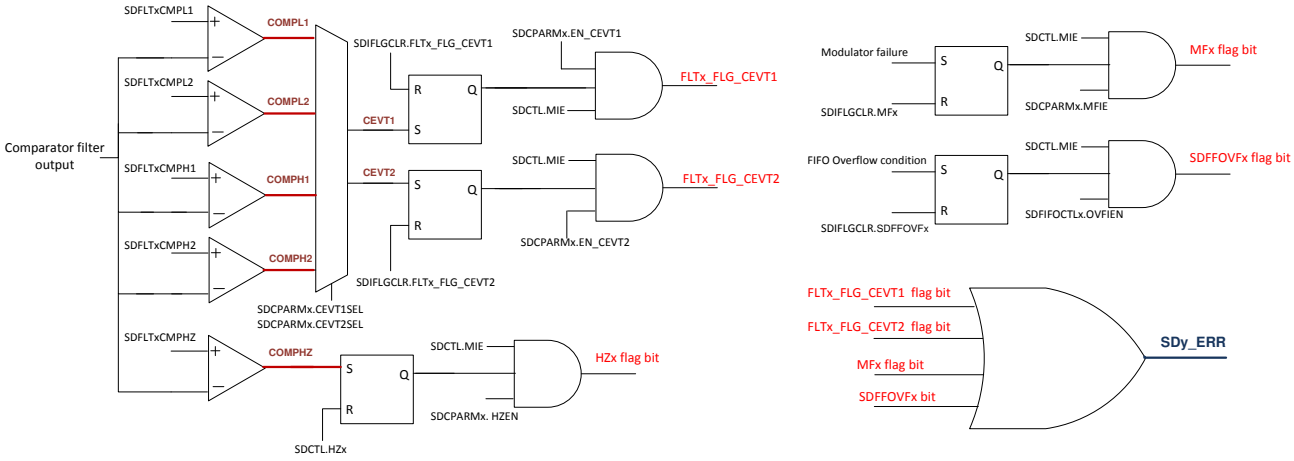
28.9 Interrupt Unit

Each SDFM can generate five CPU interrupts such as SDFM Error (SDy_ERR) and SDFM data ready (SDy_DRINT1 / SDy_DRINT2, SDy_DRINT3, SDy_DRINT4) interrupts for each filter module.

28.9.1 SDFM (SDyERR) Interrupt sources:

Figure 28-13 shows the structure of SDy_ERR interrupt. SDy_ERR interrupt can be triggered by any of these 16 events.

Figure 28-13. SDFM Error (SD_ERR) interrupt sources



NOTE

Higher Threshold (Z) comparator event (HZx) cannot be configured to trigger interrupt source. Higher Threshold (Z) comparator event (COMPHZx) is internally connected to ECAP128:1 MUX to facilitate frequency / duty cycle measurement of Threshold crossing event.

1. Comparator Event1 (CEVT1)

CEVT1 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy_ERR interrupt only if below configurations are made:

- Enable master interrupt enable (SDCTL.MIE = 1)
- Enable comparator Event1 interrupt (SDCPARMx.EN_CEVT1 = 1)

On a CEVT1 event, SDIFLG. FLTx_FLG_CEVT1 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

2. Comparator Event2 (CEVT2)

CEVT2 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy_ERR interrupt only if below configurations are made:

- Enable master interrupt enable (SDCTL.MIE = 1)
- Enable comparator event1 interrupt (SDCPARMx.EN_CEVT2 = 1)

On a CEVT2 event, SDIFLG. FLTx_FLG_CEVT2 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

3. Modulator Failure (MFx) event

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy_ERR interrupt only if below configurations are made:

- Enable master Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

4. FIFO overflow (SDFFOVFx) event

The number of filter data available in FIFO at any given point can be tracked in SDFIFOCTLx.SDFFST. If the number of words received in FIFO is greater than Max FIFO depth (16), SDFFOVFx event is generated. SDFFOVFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy_ERR interrupt only if below configurations are made:

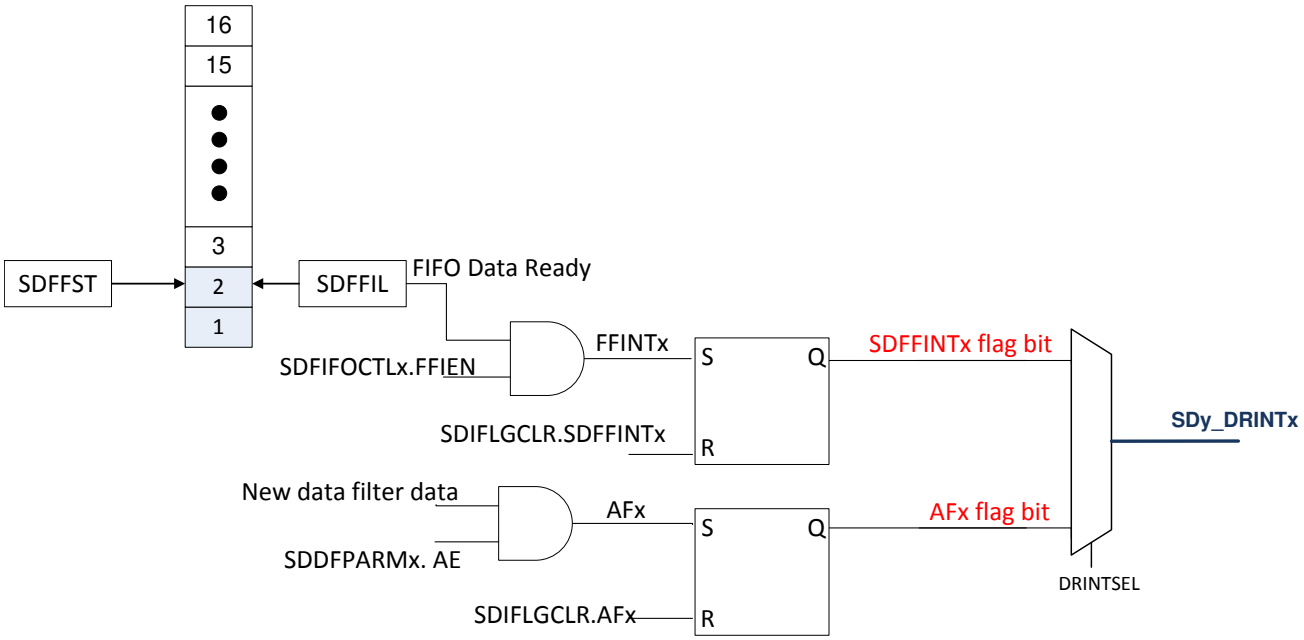
- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO overflow interrupt (Set SDFIFOCTLx.OVFIEN = 1) and
- Enable Master interrupt enable (Set SDCTL.MIE = 1)

On a SDFFOVFx event, all subsequent data (primary) filter data is lost and is not stored in FIFO. SDIFLG.SDFFOVFx flag bit is set on a FIFO overflow event and this bit can be cleared if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

28.9.2 Data Ready (DRINT) Interrupt sources:

Figure 28-14 shows the structure of interrupt SDy_DRINTx interrupt. Each SDy_DRINTx interrupt is triggered by corresponding Data Filter channel.

Figure 28-14. SDFM Data Ready (SDy_DRINTx) Interrupt



1. Data Acknowledge (AFx)

When the primary filter is ready with a new filter data, AFx event is generated. AFx events from each filter can generate its own SDy_DRINTx interrupt. This event can be configured to trigger SDy_DRINTx interrupt only if below configurations are made:

- Enable individual filter interrupts (SDDFPARMx. AE = 1)
- Select data-ready interrupt source AFx (DRINTx = AFx) (SDFIFOCTLx.DRINTSEL = 0)

On an AFx event, the SDIFLG.AFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

2. Four FIFO Data ready interrupt (SDFFINTx)

FIFO Data Ready event is generated whenever SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met. FIFO data ready events from each filter can generate its own SDy_DRINTx interrupt. This event can be configured to trigger SDy_DRINTx interrupt only if below configurations are made:

Table 28-7 shows how the DRINTx output is selected.

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1) and
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)

- Select data-Ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

Table 28-7. SDFM Data-Ready Interrupt (SDy_DRINTx) Output Selection

DRINTSEL	AE	FFIEN	FFEN	DRINTx
0	0	x	X	0
0	1	x	X	AFx
1	x	0	X	0
1	x	x	0	0
1	x	1	1	SDFFINTx

28.10 SDFM Registers

This section describes the Sigma Delta Filter registers.

28.10.1 SDFM Base Addesses

Table 28-8. SDFM Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
Sdfm1Regs	SDFM_REGS	SDFM1_BASE	0x0000_5E00	YES	YES	YES	YES	YES
Sdfm2Regs	SDFM_REGS	SDFM2_BASE	0x0000_5E80	YES	YES	YES	YES	YES

28.10.2 SDFM_REGS Registers

Table 28-9 lists the SDFM_REGS registers. All register offset addresses not listed in Table 28-9 should be considered as reserved locations and the register contents should not be modified.

Table 28-9. SDFM_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SDIFLG	SD Interrupt Flag Register		Go

Complex bit access types are encoded to fit into small table cells. Table 28-10 shows the codes that are used for access types in this section.

Table 28-10. SDFM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

28.10.2.1 SDIFLG Register (Offset = 0h) [reset = 0h]

SDIFLG is shown in Figure 28-15 and described in Table 28-11.

Return to the Summary Table.

28.10.2.2 SDIFLGCLR Register (Offset = 2h) [reset = 0h]

SDIFLGCLR is shown in Figure 28-16 and described in Table 28-12.

Return to the Summary Table.

SD Module Interrupt Flag Clear Bits:

Writing a "1" will clear the respective flag bit in the SDIFLG register.
Writes of "0" are ignored.

Note: If user writes a "1" to clear a bit on the same cycle that the hardware is trying to set the bit to "1", then hardware has priority and the bit will not be cleared.

► COMMUNICATION PERIPHERALS

The following chapters describe the communication peripherals.

29.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown below below in Figure 39-1. This Technical Reference Manual is organized into five major sections:

- C28 SYSTEM RESOURCES

  These chapters describe the C28 CPU subsystem, C28 Boot ROM, device configuration, and other system peripherals.
- ANALOG PERIPHERALS

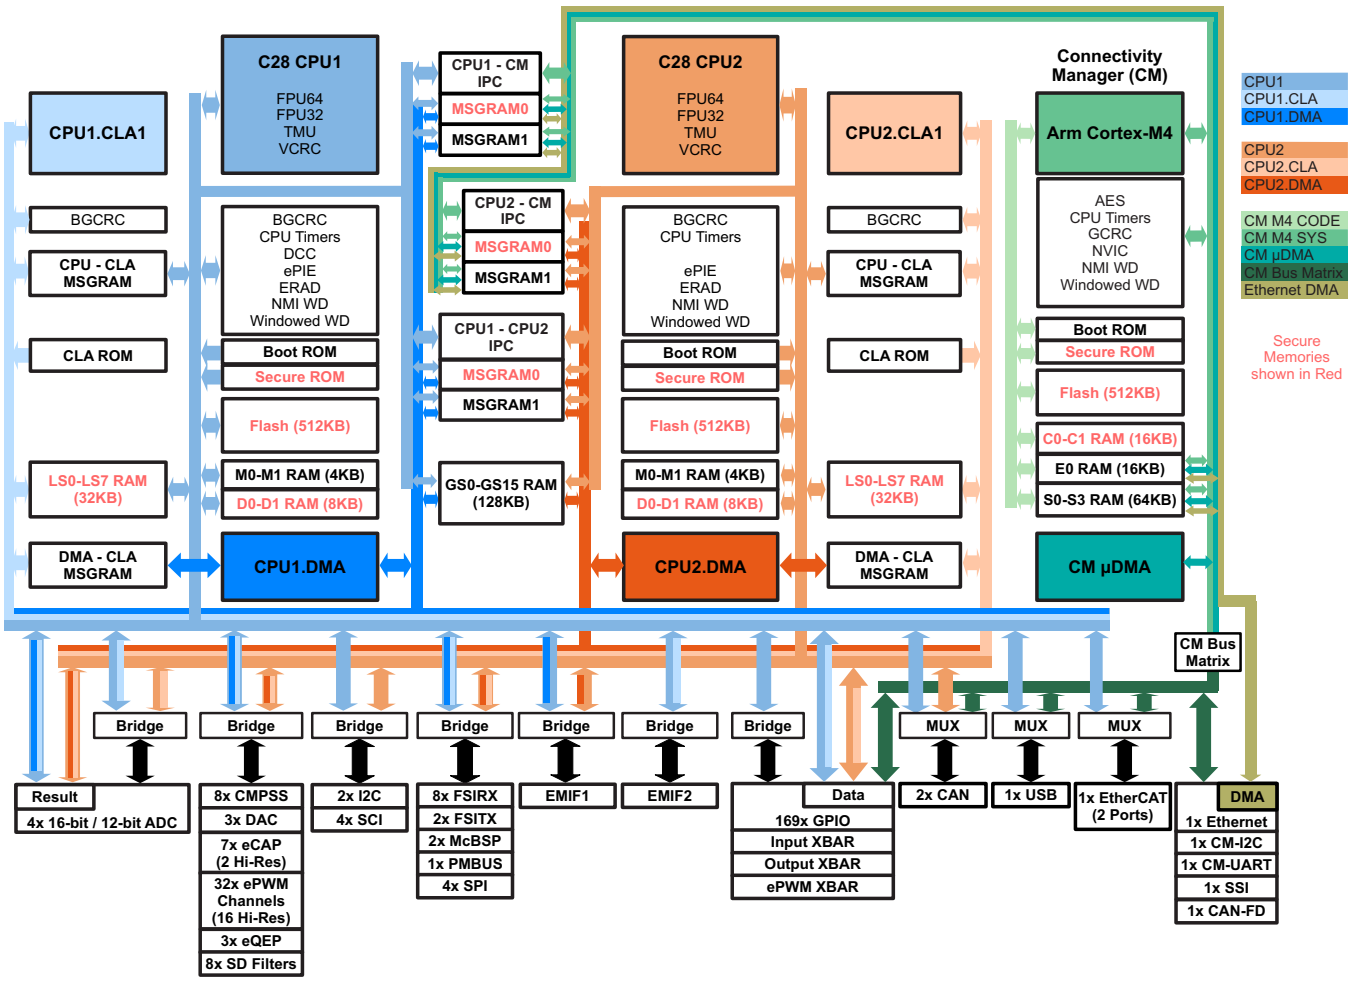
  These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.
- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.
- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C28 subsystem such as I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.
- CONNECTIVITY MANAGER (CM)

  These chapters describe the Connectivity Manager subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Figure 29-1. F2838x Block Diagram



Controller Area Network (CAN)

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol which efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

Further information can be found in the following document(s):

- *Calculator for CAN Bit Timing Parameters*

Topic **Page**

30.1 Introduction

This device uses the CAN IP known as DCAN.

30.1.1 Features

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1 Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably), each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard (11-bit) or extended (29-bit) identifier
  - Supports programmable identifier receive mask
  - Supports data and remote frames
  - Holds 0 to 8 bytes of data
  - Parity-checked configuration and data RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Message-RAM parity-check mechanism
- Two interrupt lines
- DMA support

NOTE: For a CAN bit clock of 200 MHz, the smallest bit rate possible is 7.8125 kbps.

NOTE: Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data manual) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

30.1.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

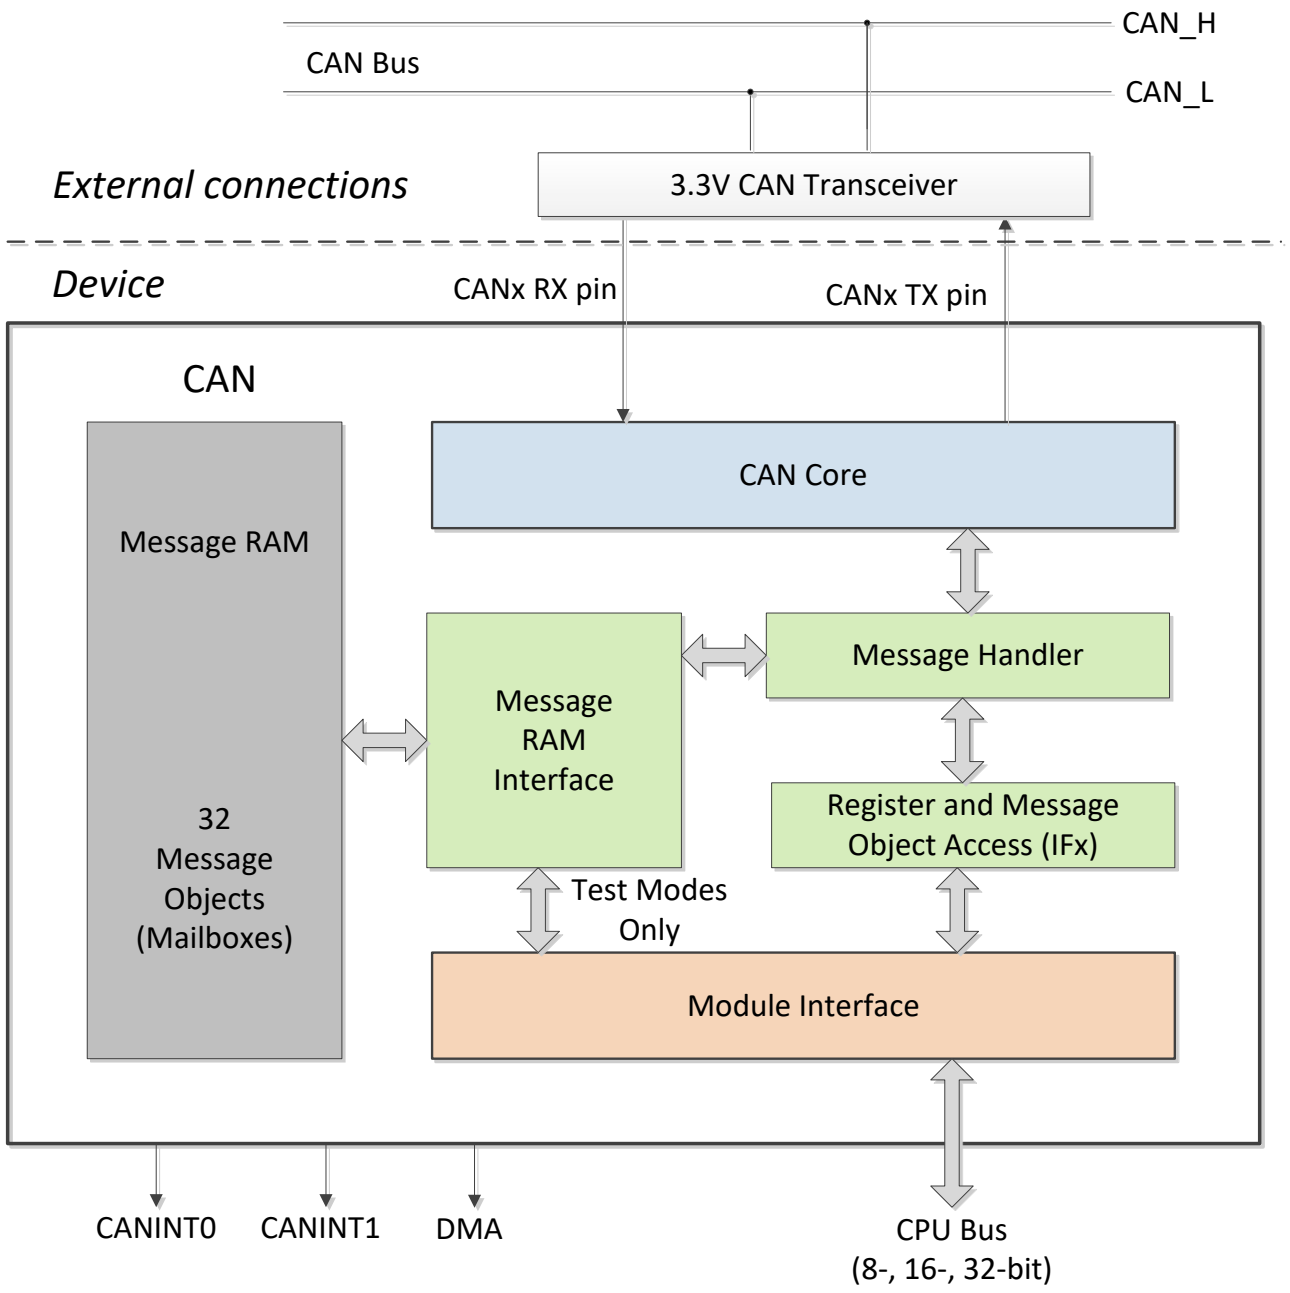
For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests as well as the generation of interrupts or DMA requests.

The register set of the CAN may be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

30.1.3 Block Diagram

Figure 30-1. CAN Block Diagram



30.1.3.1 CAN Core

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. It handles all ISO 11898-1 protocol functions.

30.1.3.2 Message Handler

The message handler is a state machine which controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. It also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

30.1.3.3 Message RAM

The CAN message RAM enables the storage of 32 CAN messages.

30.1.3.4 Registers and Message Object Access (IFx)

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through Interface registers.

Three Interface register sets control the CPU read and write accesses to the Message RAM. There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also Section 30.14. The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

30.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

30.3 Address/Data Bus Bridge

The CAN module uses a special addressing scheme to support byte accesses. It is recommended to only use 32-bit accesses to the CAN registers using the *HWREG_BP()* macro which uses the *__byte_peripheral_32()* intrinsic. If 16-bit accesses are to be used, the lower 16 bits should be written to the register's address, and the upper 16 bits should be written to the register's address, plus 2.

Because of the bus bridge, the view of the CAN module's register space through a Code Composer Studio (CCS) memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses should be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view.; odd addresses from the module are not displayed.

Table 30-1. CAN Register Access From Software

CAN Register Space			C28x 8-Bit		C28x 16-Bit		C28x 32-Bit	
Address	**Reg. Name**	**Data**	**Access**	**Data**	**Access**	**Data**	**Address**	**Data**

30.4 Operating Modes

30.4.1 Initialization

The initialization mode is entered either by software (by setting the **Init** bit in the CAN_CTL register), by hardware reset, or by going bus-off. While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high). The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

To initialize the CAN Controller, the CPU has to configure the CAN Bit timing and those message objects which have to be used for CAN communication. Message objects which are not needed, can be deactivated with their MsgVal bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and CCE bits in the CAN Control register are set.

Clearing the Init bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before it can take part in bus activities and start the message transfer. For more details see Section 30.13 .

The initialization of the message objects is independent of the Init bit; however, all message objects should be configured to particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering will be applied to it when the modified message object number is same or smaller than the previously found message object. This assures data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

30.4.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes itself to the CAN bus and is ready for communication.

Received messages are stored into their appropriate message objects if they pass acceptance filtering. The whole message (MSGID, DLC, and up to eight data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits which are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the Interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority. Messages may be updated or set to 'not valid' at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

30.4.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed

By default, this automatic retransmission is enabled. It can be disabled by setting the DAR bit in the CAN Control register. Further details to this mode are provided in Section 30.12.3.

30.4.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module will stay in bus-off state.

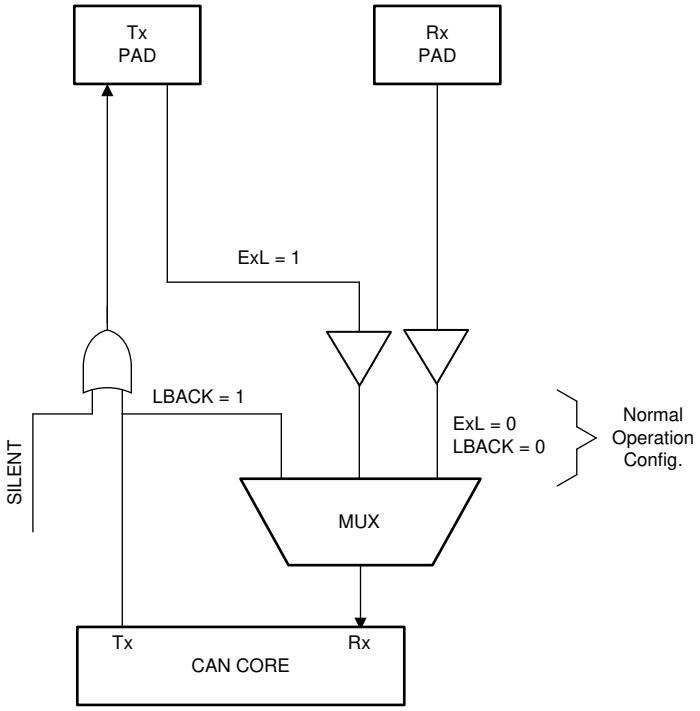
The CAN provides an automatic auto-bus-on feature which is enabled by the ABO bit. If set, the CAN will automatically start the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

NOTE: If the CAN module goes Bus-Off due to multiple CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit is cleared by the application (or due to the auto-bus-on feature), the device will wait for 129 occurrences of Bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the Init bit. At the end of the bus-off recovery sequence, the error counters will be reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

30.4.3 Test Modes

The CAN module provides several test modes which are mainly intended for self-test purposes. The diagram below aids in understanding the various test modes. It should be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. For the sake of brevity, this diagram does not include the GPIO muxing or the I/O buffers.

Figure 30-2. CAN_MUX



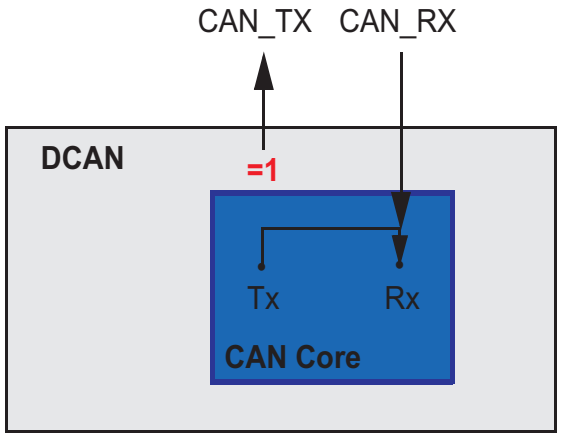
For all test modes, the Test bit in the CAN Control register needs to be set to 1 to enable write access to the CAN_TEST register.

30.4.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The CAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, the received frames are internally routed to the CAN Core.

Figure 30-3 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the **Silent** bit in test register (CAN_TEST), to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 30-3. CAN Core in Silent Mode



30.4.3.2 Loopback Mode

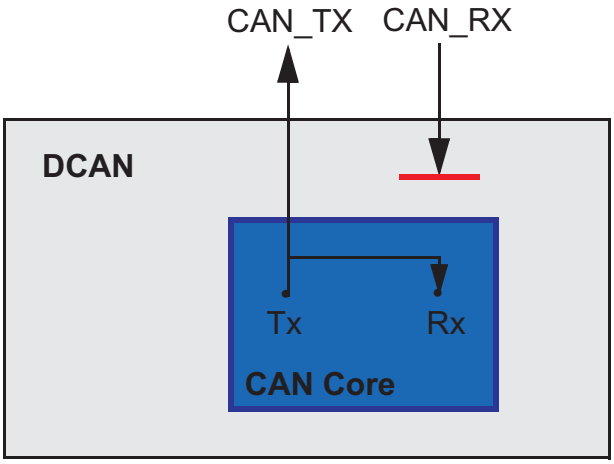
The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 30-4 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode. Loopback mode can be activated by setting bit **LBack** in the CAN_TEST register to 1.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN Core are disregarded. For including these into the testing, see Section 30.4.3.3.

Figure 30-4. CAN Core in Loopback Mode



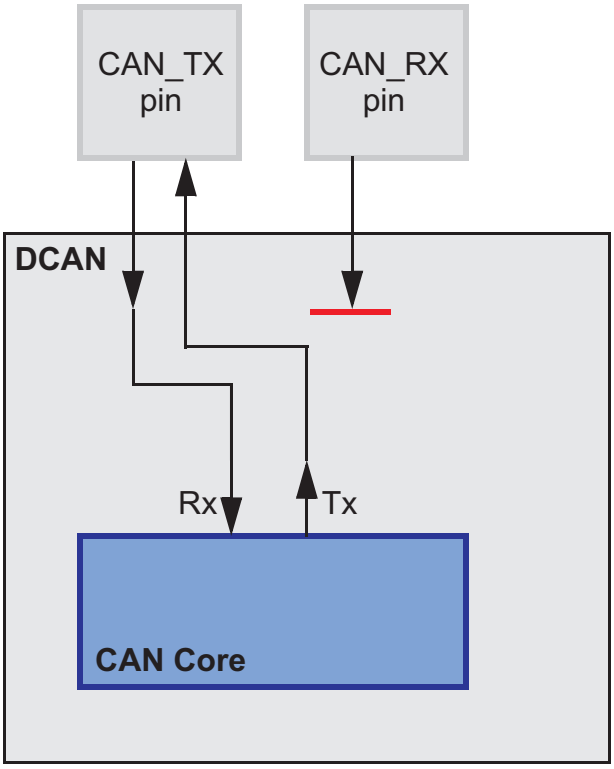
30.4.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN Core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to the CAN Core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the **ExL** bit in Test Register to 1.

Figure 30-5 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in external loopback mode.

NOTE: When loopback mode is active (LBack bit set), the ExL bit will be ignored.

Figure 30-5. CAN Core in External Loopback Mode

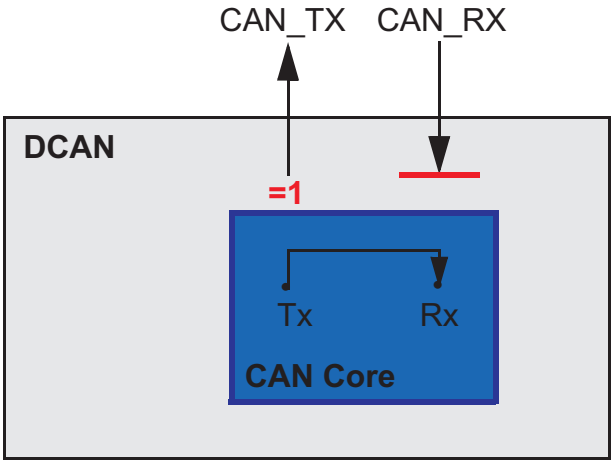


30.4.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN Core and no dominant bits will be sent on the CAN_TX pin.

Figure 30-6 shows the connection of the signals CAN_TX and CAN_RX to the CAN Core in case of the combination of loopback mode with silent mode.

Figure 30-6. CAN Core in Loopback Combined with Silent Mode



30.5 Multiple Clock Source

The CAN bit timing clock is normally derived from the system clock (SYSCLK). If desired, the bit clock can be derived directly from the external clock source (XTAL).

The System Control chapter of this document and the device data manual provide for more information on how to configure the relevant clock source registers in the system module.

NOTE: The CAN core has to be programmed to at least eight clock cycles per bit time. To achieve a transfer rate of 1 Mbps an oscillator frequency of 8 MHz or higher has to be used.

30.6 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID / Int1ID in the Interrupt register. When no interrupt is pending, the register will hold the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk and LEC by reading the Error and Status Register, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID / INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine which reads the message from the interrupt source, may also read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 Command register). When IntPnd is cleared, the Interrupt register will point to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN_GLB_INT_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt via CAN_GLB_INT_CLR and PIEACK.

30.6.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in Section 30.15.1. Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

Note that writing to the IntPnd bit in the CAN_IFnMCTL registers can force an interrupt.

30.6.2 Status Change Interrupts

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN_CTL Register.

30.6.3 Error Interrupts

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN_CTL register.

30.6.4 PIE Nomenclature for DCAN Interrupts

Table 30-3 shows the PIE nomenclature for the interrupts.

Table 30-3. PIE Nomenclature for Interrupts

Interrupt	CANA	CANB
CANINT0	CANA_0	CANB_0
CANINT1	CANA_1	CANB_1

30.6.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in Figure 30-7 and Figure 30-8.

Figure 30-7. CAN Interrupt Topology 1

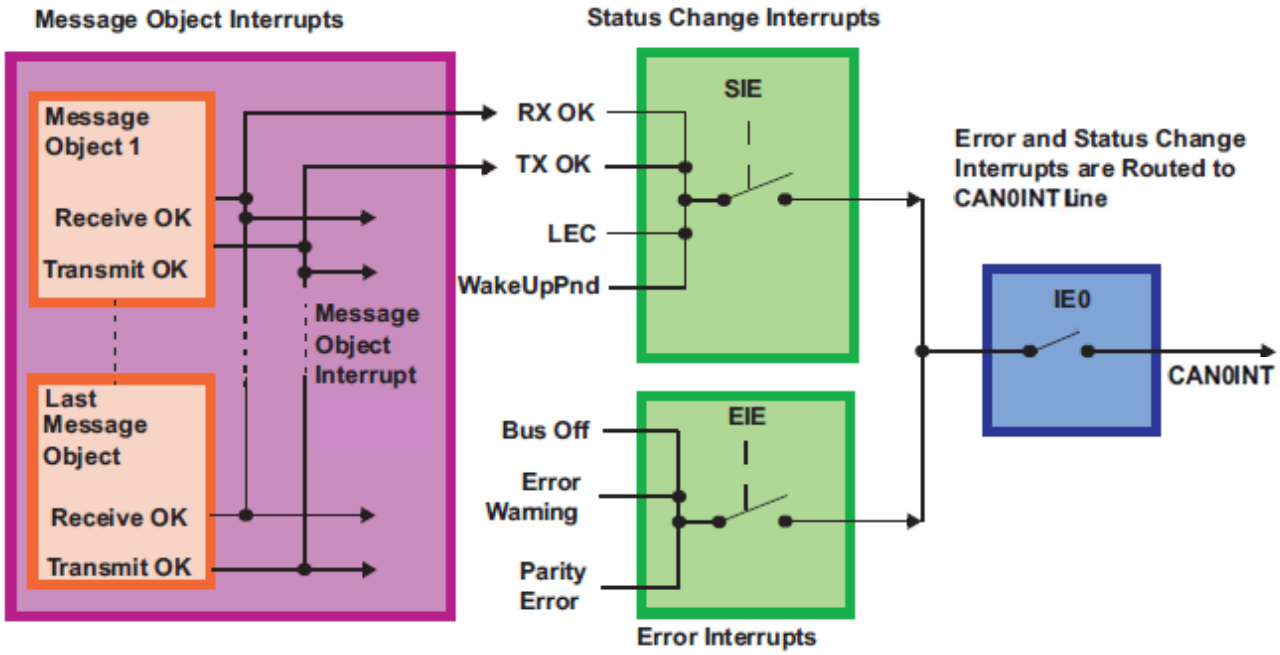


Figure 30-8. CAN Interrupt Topology 2

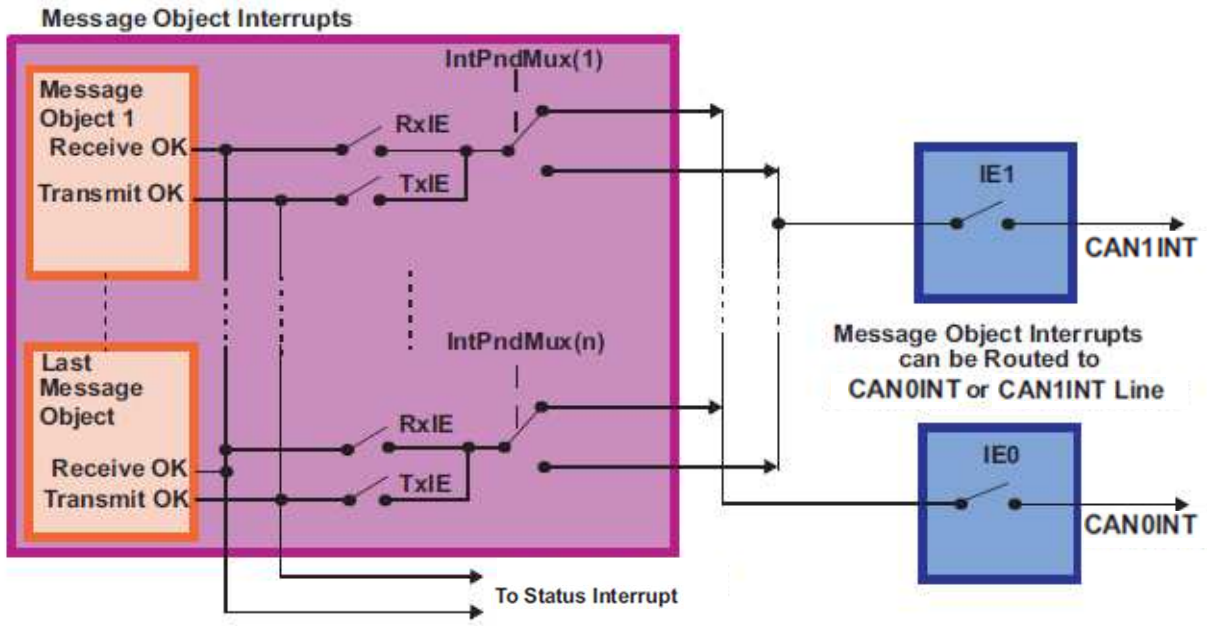


30.7 DMA Functionality

The CAN module provides three DMA trigger outputs, one for each of the three Interface Registers IF1, IF2 and IF3. These can be enabled using the DE1, DE2, and DE3 bits in the CAN_CTL register.

The Update of IF1 and IF2 registers will be initiated by a write access to the IF1 and IF2 Command registers, respectively. Once enabled, setting the DMAActive bit in the IF1CMD or IF2CMD registers will cause a DMA request the next time the corresponding interface becomes available.

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update. That is, when IF3 DMA requests are enabled, all IF3 updates will trigger a DMA request.

When a DCAN internal IFx update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers; that is, DMA requests are cleared after the first read or write access to an IF register set.

30.8 Parity Check Mechanism

The CAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in Message RAM, one parity bit will be calculated.

Parity information is stored in the Message RAM on write accesses and will be checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN Control register. In case of a disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the CAN. A parity bit will be set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

30.8.1 Behavior on Parity Error

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object will be checked. If a parity error is detected, the PER bit in the Error and Status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

30.9 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit will wait until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect. Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization (see Section 30.15.3).

NOTE: During debug mode, the Message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in Debug mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers (clear of DMA Active flag by r/w)

30.10 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects should be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see Section 30.11.

For the configuration of the Bit Timing, see Section 30.13.2.

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to '0' by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted via the CAN bus.

The CPU may enable the interrupt lines (setting IE0 and IE1 to '1') at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication may be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with IntPnd = '1'. It is updated even if the interrupt lines to the CPU are disabled (IE0 / IE1 are zero).

The CPU may poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData registers and the Transmission Request registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers; all Receive Objects are grouped at the high numbers.

30.11 Configuration of Message Objects

The entire Message RAM should to be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

30.11.1 Configuration of a Transmit Object for Data Frames

Figure 30-9 shows how a transmit object can be initialized.

Figure 30-9. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.
- The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.
- If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.
- If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.
- The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details see Section 30.12.8. Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

30.11.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object will cause the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

30.11.3 Configuration of a Single Receive Object for Data Frames

Figure 30-10 shows how a receive object for data frames can be initialized.

Figure 30-10. Initialization of a Single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- When the message handler stores a data frame in the message object, it will store the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.
- The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register will be overwritten by the bits of the stored data frame.

- If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the Arbitration bits will be triggered. The content of the Arbitration bits may change if the Mask bits are used (UMask = '1') for acceptance filtering.

30.11.4 Configuration of a Single Receive Object for Remote Frames

Figure 30-11 shows how a receive object for remote frames can be initialized.

Figure 30-11. Initialization of a single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

- Receive objects for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer, see Section 30.11.5.
- UMask must be set to '1'. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details see Section 30.12.8.
- The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0'.
- The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.
- If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

30.11.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to zero. The EoB bits of the last message object of a FIFO buffer is set to one, configuring it as the end of the block.

30.12 Message Handling

When initialization is finished, the CAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages are accepted for the same message object will be overwritten. Messages may be read interrupt-driven or after polling of NewDat.

30.12.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. It performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).

- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

30.12.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

30.12.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN Control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching Transmit Object the RmtEn bit is set.

30.12.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MsgVal nor TxRqst have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see Section 30.12.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

30.12.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however it will not be repeated if it is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

30.12.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

30.12.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

30.12.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

1. Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'

   The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'

   The remote frame is ignored, this message object remains unchanged.
3. Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'

   The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

30.12.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface registers, the data consistency is guaranteed by the message handler state machine.

Typically the CPU will write 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination will transfer the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst will not be automatically reset.

30.12.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

30.12.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifier(s). Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are '0', in the last one the EoB bit is '1'.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is '0' the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to '0', all further messages for this FIFO Buffer will be written into the last message object of the FIFO Buffer (EoB = '1') and therefore overwrite previous messages in this message object.

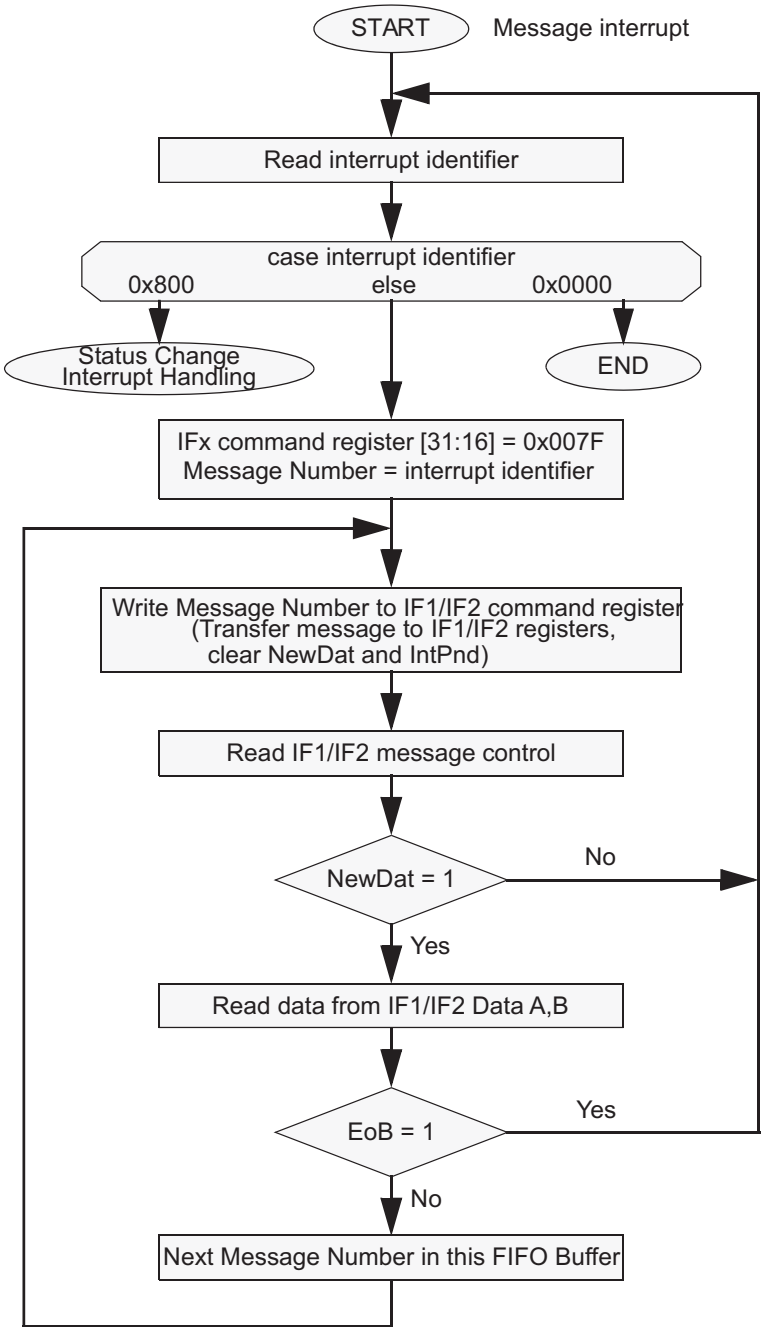
30.12.12 Reading from a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO Buffer before the application program is required (in order to avoid the loss of data) to empty the buffer. A FIFO Buffer of length N will store N-1 plus the last received message since last time it was cleared. A FIFO Buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 30-12.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise true FIFO functionality cannot be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO Buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

Figure 30-12. CPU Handling of a FIFO Buffer (Interrupt Driven)



30.13 CAN Bit Timing

The CAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The Bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods (F_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

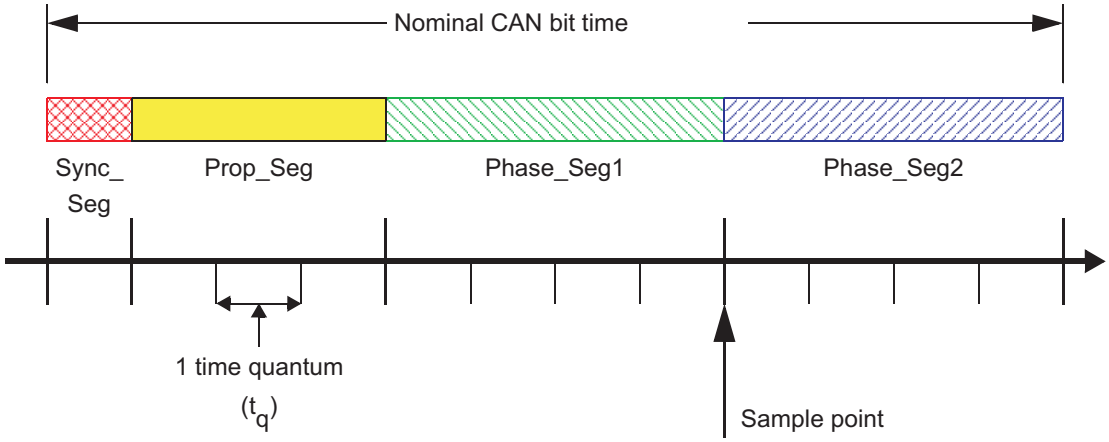
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

30.13.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see Figure 30-13):

- Synchronization Segment (Sync_Seg)
- Propagation Time Segment (Prop_Seg)
- Phase Buffer Segment 1 (Phase_Seg1)
- Phase Buffer Segment 2 (Phase_Seg2)

Figure 30-13. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \frac{\text{Baud Rate Prescaler}}{\text{CAN\_CLK}}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 30-4 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 30-4. Programmable Ranges Required by CAN Protocol

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either phase buffer segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

30.13.1.1 Synchronization Segment

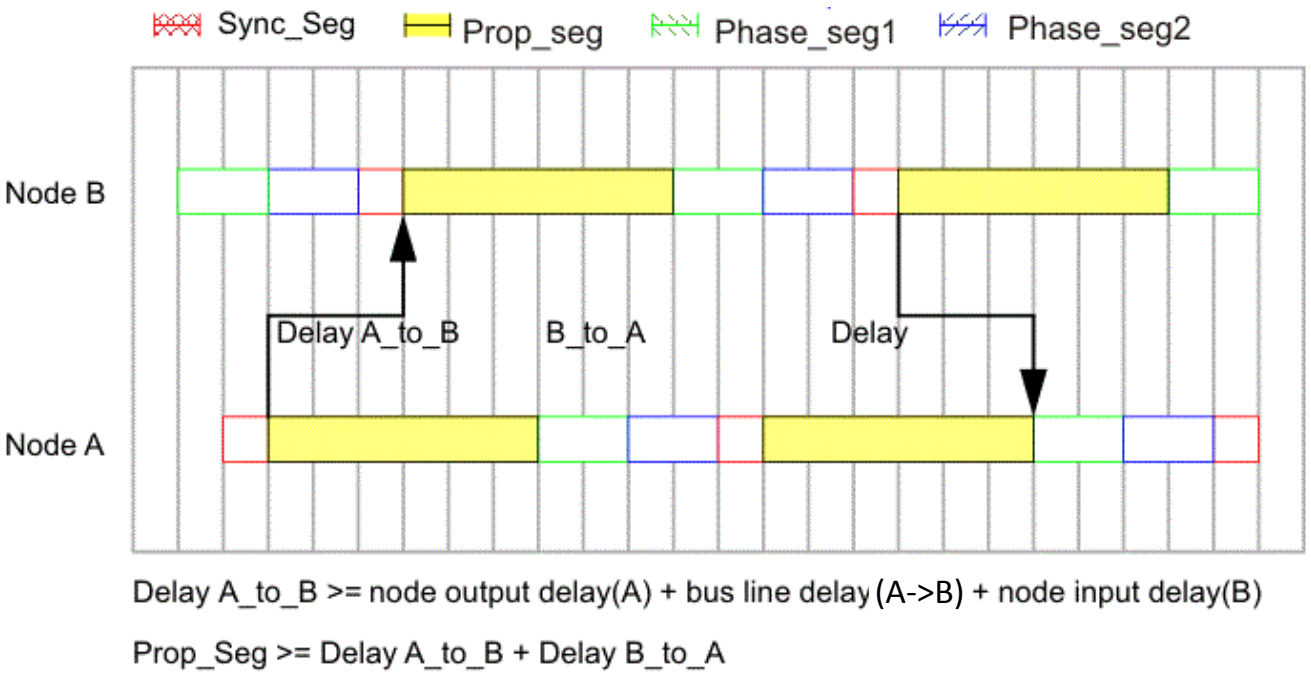
The Synchronization Segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

30.13.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 30-14 shows the phase shift and propagation times between two CAN nodes.

Figure 30-14. The Propagation Time Segment



In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay(B_to_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the Bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

30.13.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg, otherwise its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

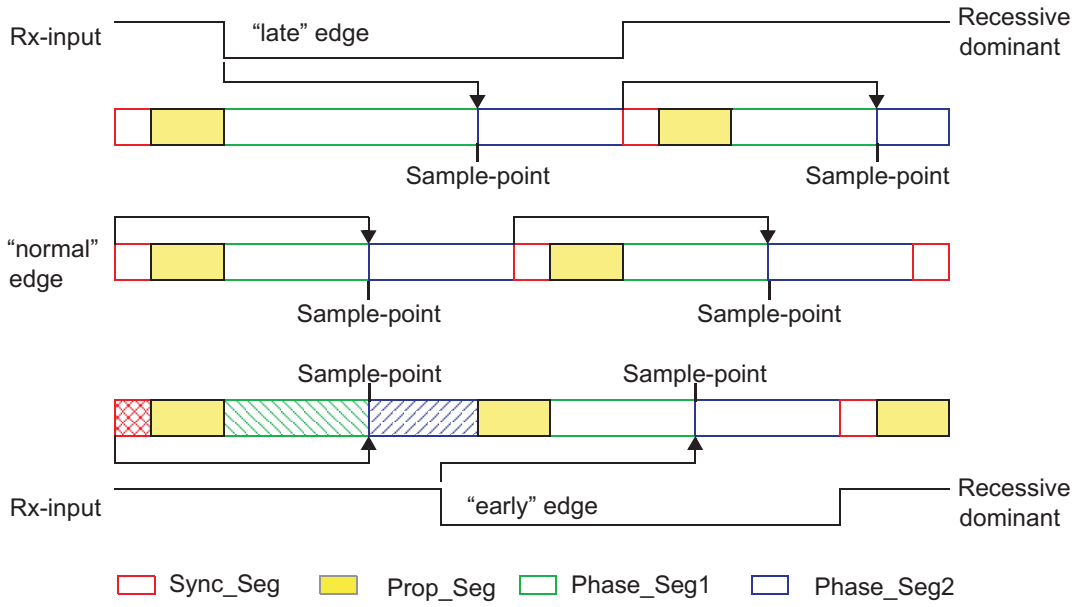
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The "leading" transmitter does not necessarily win the arbitration, therefore the receivers have to synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator's tolerance range.

The examples in Figure 30-15 show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

Figure 30-15. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the "late" edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the "early" edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

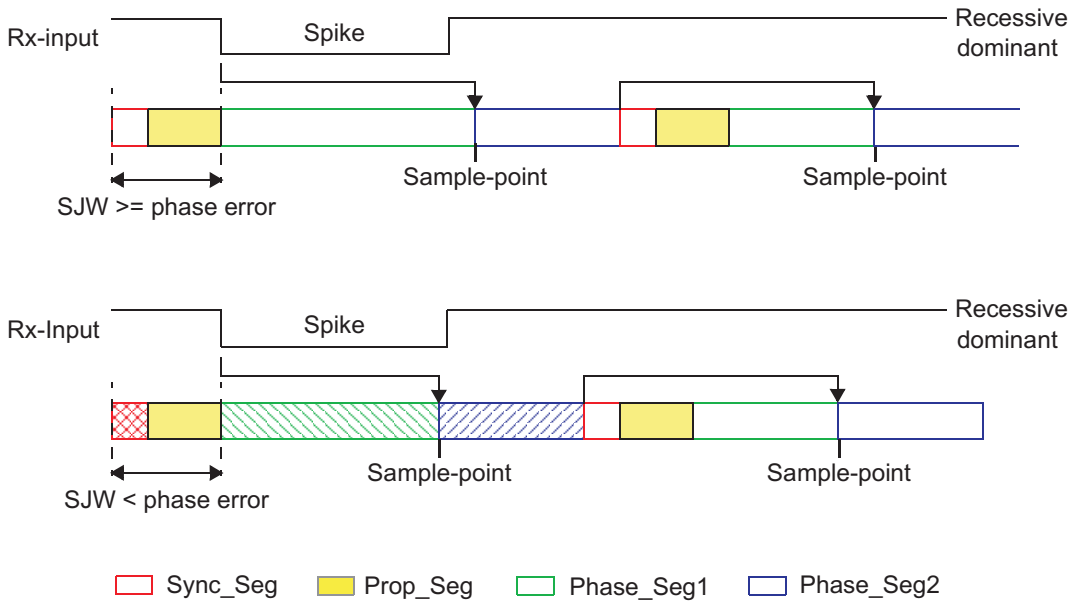
In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an "*early*" edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

The examples in Figure 30-16 show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 30-16. Filtering of Short Dominant Spikes



30.13.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with

$(1 - df) \bullet f_{nom} \leq f_{osc} \leq (1 + df) \bullet f_{nom}$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

(9)

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit\_time}$$

(10)

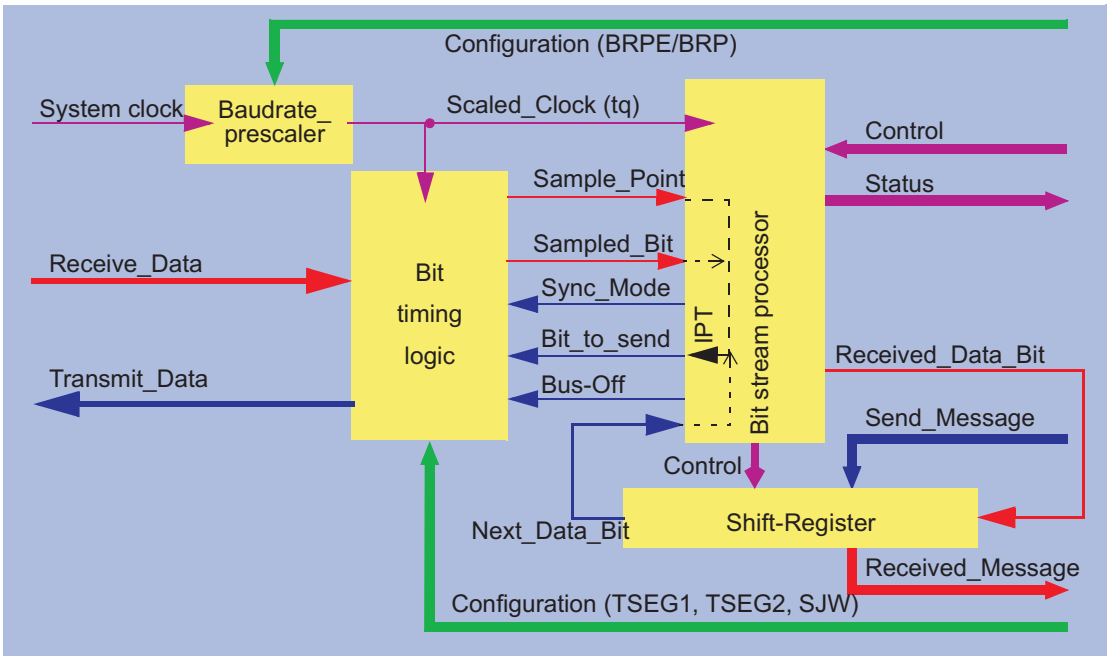
It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

30.13.2 Configuration of the CAN Bit Timing

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 30-17).

Figure 30-17. Structure of the CAN Core's CAN Protocol Controller



In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n-1] are programmed. That way, for example, SJW (functional range of [1…4]) is represented by only two bits.

Therefore the length of the Bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP.

The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is 0 t_q for the CAN.

Generally, the IPT is CAN controller specific, but may not be longer than 2 t_q. The IPT length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

30.13.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

NOTE: 8 MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the Baud Rate Prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time - Prop_Seg - 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of 4 and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 30.13.1.4.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

(Phase_Seg2-1)&(Phase_Seg1+Prop_Seg-1)&

(SynchronizationJumpWidth-1)&(Prescaler-1)

30.13.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

t_q	100	ns	=	t_{CAN_CLK}
delay of bus driver	90	ns	=	
delay of receiver circuit	40	ns	=	
delay of bus line (40m)	220	ns	=	
t_{Prop}	700	ns	=	2*delays = 7 • t_q
t_{SJW}	100	ns	=	1 • t_q
t_{TSeg1}	800	ns	=	t_{Prop} + t_{SJW}
t_{TSeg2}	100	ns	=	Information Processing Time + 1 • t_q
$t_{Sync-Seg}$	100	ns	=	1 • t_q

bit time	1000	ns	=	$t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	0.35	%	=	$\frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$ $= \frac{0.1\,\mu s}{2((13 \times 1\,\mu s) - 0.1\,\mu s)}$

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$&$(8\text{-}1)_4$&$(1\text{-}1)_2$&$(1\text{-}1)_6$, so the Bit Timing Register is programmed to = 0x00000700.

30.13.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

t_q	1	µs	=	2 • t_{CAN_CLK}
delay of bus driver	200	ns	=	
delay of receiver circuit	80	ns	=	
delay of bus line (40m)	220	ns	=	
t_{Prop}	1	µs	=	1 • t_q
t_{SJW}	4	µs	=	4 • t_q
t_{TSeg1}	5	µs	=	$t_{Prop} + t_{SJW}$
t_{TSeg2}	4	µs	=	Information Processing Time + 4 • t_q
$t_{Sync\text{-}Seg}$	1	µs	=	1 • t_q
bit time	10	µs	=	$t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	1.58	%	=	$\frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$ $= \frac{4\,\mu s}{2((13 \times 10\,\mu s) - 4\,\mu s)}$

In this example, the concatenated bit time parameters are $(4\text{-}1)_3$&$(5\text{-}1)_4$&$(4\text{-}1)_2$&$(2\text{-}1)_6$, so the Bit Timing register is programmed to = 0x000034C1.

30.14 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modifywrite cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set which are not selected in the Command Register, will be left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see Section 30.15.1) or parts of the message object may be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

That being said, there is one condition that can cause a write access to the message RAM to be lost. If MsgVal = 1 for the message object which is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM may be lost. The reason for this is that it might happen that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when it is in the process of receiving a message for the same message object.

To avoid this issue with receive mail boxes, reset MsgVal before changing any of the following: Id28-0, Xtd, Dir, DLC3-0, RxIE, TxIE, RmtEn, EoB, Umask, Msk28-0, MXtd, and MDir.

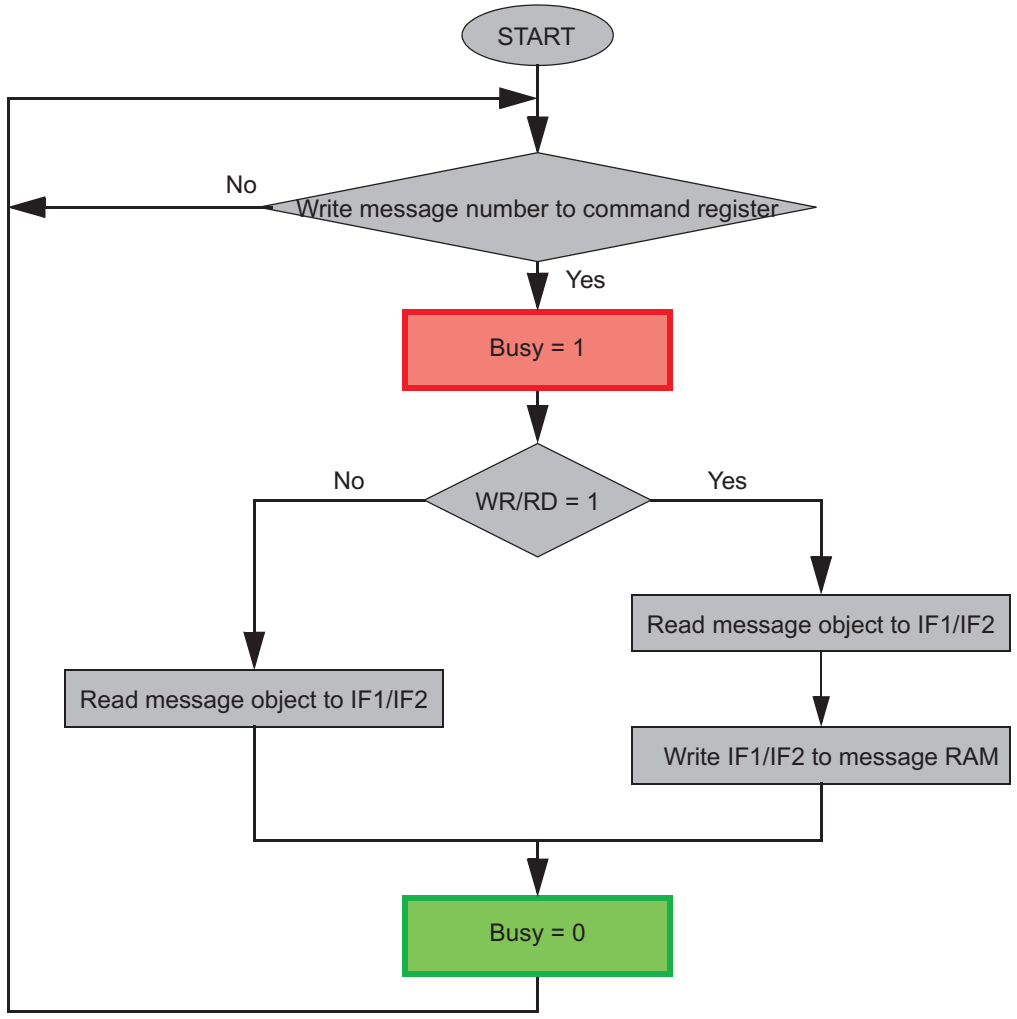
To avoid this issue with transmit mail boxes, reset MsgVal before changing any of the following: Dir, RxIE, TxIE, RmtEn, EoB, Umask, Msk28-0, MXtd, and MDir. Other fields not listed above, like Data, may be changed without fear of losing a write to the message RAM.

30.14.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register will be overwritten by values taken from the other IFx registers. Is the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register will be copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to '1'. After the transfer has completed, the Busy bit is set back to '0' (see Figure 30-18).

Figure 30-18. Data Transfer Between IF1 / IF2 Registers and Message RAM



30.14.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA will be requested. The DMA request stays active until the first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in the CAN Control register.

NOTE: The IF3 register set can not be used for transferring data into message objects.

30.15 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed via the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

30.15.1 Structure of Message Objects

Figure 30-19 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Figure 30-19. Structure of a Message Object

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 30-5. Message Object Field Descriptions

Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code DLC[3:0] are changed.
UMask		Use Acceptance Mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message Identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier Mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
		Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28xx devices, where a "1" means the corresponding bit is NOT used for filtering, and "0" means it is used.

Table 30-5. Message Object Field Descriptions (continued)

Name	Value	Description
Xtd		Extended Identifier
	0	The 11-bit ("standard") identifier will be used for this message object.
	1	The 29-bit ("extended") identifier will be used for this message object.
MXtd		Mask Extended Identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message Direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
MDir		Mask Message Direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of Block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New Data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message Lost (only valid for Message Objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive Interrupt Enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit Interrupt Enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt Pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote Enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
		Note: See Section 30.12.8 for details on the setup of RmtEn and UMask for remote frames.
TxRqst		Transmit Request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.

Table 30-5. Message Object Field Descriptions (continued)

Name	Value	Description
DLC[3:0]		Data length code
	0-8	Data frame has 0-8 data bytes.
	9-15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN Core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

30.15.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) * 0x20.

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

NOTE: '0' is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object may overwrite an implemented message object.

Message Object number 1 has the highest priority.

Table 30-6. Message RAM Addressing in Debug Mode

Message Object Number	Offset From Base Address	Word Number	Debug Mode [1]
last implemented (here:32)	0x0000	1	Parity
	0x0004	2	MXtd,MDir,Mask
	0x0008	3	Xtd,Dir,ID
	0x000C	4	Ctrl
	0x0010	5	Data Bytes 3-0
	0x0014	6	Data Bytes 7-4
1	0x0020	1	Parity
	0x0024	2	MXtd,MDir,Mask
	0x0028	3	Xtd,Dir,ID
	0x002C	4	Ctrl
	0x0030	5	Data Bytes 3-0
	0x0034	6	Data Bytes 7-4

(1) See Section 30.15.3.

Table 30-6. Message RAM Addressing in Debug Mode (continued)

Message Object Number	Offset From Base Address	Word Number	Debug Mode [1]
2	0x0040	1	Parity
	0x0044	2	MXtd,MDir,Mask
	0x0048	3	Xtd,Dir,ID
	0x004C	4	Ctrl
	0x0050	5	Data Bytes 3-0
	0x0054	6	Data Bytes 7-4
…	…	…	…
31	0x03E0	1	Parity
	0x03E4	2	MXtd,MDir,Mask
	0x03E8	3	Xtd,Dir,ID
	0x03EC	4	Ctrl
	0x03F0	5	Data Bytes 3-0
	0x03F4	6	Data Bytes 7-4

30.15.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM will be memory mapped. This allows the external debug unit to access the Message RAM.

NOTE: During debug mode, the Message RAM cannot be accessed via the IFx register sets.

Figure 30-20. Message RAM Representation in Debug Mode

Complex bit access types are encoded to fit into small table cells. Table 30-10 shows the codes that are used for access types in this section.

Table 30-10. CAN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

30.16.2.1 CAN_CTL Register (Offset (x8) = 0h, Offset (x16) = 0h) [reset = 1401h]

CAN_CTL is shown in Figure 30-21 and described in Table 30-11.

Return to the Summary Table.

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

Bit	Field	Type	Reset	Description
16	INITDBG	R	0h	Debug Mode Status Bit: This bit indicates the internal init state for a debug access 0 Not in debug mode, or debug mode requested but not entered. 1 Debug mode requested and internally entered the CAN module is ready for debug accesses. Reset type: SYSRSn
15	SWR	R/W	0h	Software Reset Enable Bit: This bit activates the software reset. 0 Normal Operation. 1 Module is forced to reset state. This bit will get cleared automatically one clock cycle after execution of software reset. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR bit. This bit is EALLOW protected. Note: This bit is write-protected by Init bit Reset type: SYSRSn
14	RESERVED	R	0h	Reserved
13-10	PMD	R/W	5h	Parity on/off 0101 Parity function disabled Any other value - Parity function enabled Reset type: SYSRSn
9	ABO	R/W	0h	Auto-Bus-On Enable 0 The Auto-Bus-On feature is disabled 1 The Auto-Bus-On feature is enabled Reset type: SYSRSn
8	IDS	R/W	0h	Interruption Debug Support Enable 0 When Debug mode is requested, the CAN module will wait for a started transmission or reception to be completed before entering Debug mode 1 When Debug mode is requested, the CAN module will interrupt any transmission or reception, and enter Debug mode immediately. Reset type: SYSRSn
7	Test	R/W	0h	Test Mode Enable 0 Disable Test Mode (Normal operation) 1 Enable Test Mode Reset type: SYSRSn
6	CCE	R/W	0h	Configuration Change Enable 0 The CPU has no write access to the configuration registers. 1 The CPU has write access to the configuration registers (when Init bit is set). Reset type: SYSRSn
5	DAR	R/W	0h	Disable Automatic Retransmission 0 Automatic Retransmission of "not successful" messages enabled. 1 Automatic Retransmission disabled. Reset type: SYSRSn
4	RESERVED	R	0h	Reserved
3	EIE	R/W	0h	Error Interrupt Enable 0 Disabled - PER, BOff and EWarn bits cannot generate an interrupt. 1 Enabled - PER, BOff and EWarn bits can generate an interrupt at CANINT0 line and affect the Interrupt Register. Reset type: SYSRSn
2	SIE	R/W	0h	Status Change Interrupt Enable 0 Disabled - RxOk, TxOk and LEC bits cannot generate an interrupt. 1 Enabled - RxOk, TxOk and LEC can generate an interrupt on the CANINT0 line Reset type: SYSRSn

Table 30-11. CAN_CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	IE0	R/W	0h	Interrupt line 0 Enable 0 CANINT0 is disabled. 1 CANINT0 is enabled. Interrupts will assert CANINT0 line to 1 line remains active until pending interrupts are processed. Reset type: SYSRSn
0	Init	R/W	1h	Initialization Mode This bit is used to keep the CAN module inactive during bit timing configuration and message RAM initialization. It is set automatically during a bus off event. Clearing this bit will not shorten the bus recovery time. 0 CAN module processes messages normally 1 CAN module ignores bus activity Reset type: SYSRSn

30.16.2.2 CAN_ES Register (Offset (x8) = 8h, Offset (x16) = 4h) [reset = 7h]

CAN_ES is shown in Figure 30-22 and described in Table 30-12.

Return to the Summary Table.

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

31-11	RESERVED	R	0h	Reserved
10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Reserved
8	PER	R	0h	Parity Error Detected: This bit will be reset after the CPU reads the register. 0 No parity error has been detected since last read access. 1 The parity check mechanism has detected a parity error in the Message RAM. Reset type: SYSRSn
7	BOff	R	0h	Bus-off Status Bit: 0 The CAN module is not in Bus-Off state. 1 The CAN module is in Bus-Off state. Reset type: SYSRSn
6	EWarn	R	0h	Warning State Bit: 0 Both error counters are below the error warning limit of 96. 1 At least one of the error counters has reached the error warning limit of 96. Reset type: SYSRSn
5	EPass	R	0h	Error Passive State 0 On CAN Bus error, the CAN could send active error frames. 1 The CAN Core is in the error passive state as defined in the CAN Specification. Reset type: SYSRSn

Table 30-12. CAN_ES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	RxOk	R	0h	Reception status Bit: This bit indicates the status of reception. The bit will be reset after the CPU reads the register. 0 No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events. 1 A message has been successfully received since the last time when this bit was reset by a read access of the CPU. This bit will be set independent of the result of acceptance filtering. Reset type: SYSRSn
3	TxOk	R	0h	Transmission status Bit: This bit indicates the status of transmission. The bit will be reset after the CPU reads the register. 0 No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events. 1 A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was cleared by a read access of the CPU. Reset type: SYSRSn
2-0	LEC	R	7h	Last Error Code The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register. 0 No Error 1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 2 Form Error: A fixed format part of a received frame has the wrong format. 3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node. 4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'. Reset type: SYSRSn

30.16.2.3 CAN_ERRC Register (Offset (x8) = 10h, Offset (x16) = 8h) [reset = 0h]

CAN_ERRC is shown in Figure 30-23 and described in Table 30-13.

Return to the Summary Table.

This register reflects the value of the Transmit and Receive error counters

Figure 30-23. CAN_ERRC Register

7-0	TEC	R	0h	Transmit Error Counter Actual state of the Transmit Error Counter. (values from 0 to 255). Reset type: SYSRSn

30.16.2.4 CAN_BTR Register (Offset (x8) = 18h, Offset (x16) = Ch) [reset = 2301h]

CAN_BTR is shown in Figure 30-24 and described in Table 30-14.

Return to the Summary Table.

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods.

Table 30-15. CAN_INT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	INT1ID	R	0h	Interrupt 1 Cause 0x00 No interrupt is pending. 0x01-0x20 Number of message object (mailbox) which caused the interrupt. 0x21-0xFF Unused. If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. Note: The CANINT1 interrupt line remains active until INT1ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. A message interrupt is cleared by clearing the mailbox's IntPnd bit. Among the message interrupts, the mailbox's interrupt priority decreases with increasing message number. Reset type: SYSRSn
15-0	INT0ID	R	0h	Interrupt 0 Cause 0x0000 - No interrupt is pending. 0x0001 - 0x0020 - Number of message object which caused the interrupt. 0x0021 - 0x7FFF - Unused. 0x8000 - Error and Status Register value is not 0x07. 0x8001 - 0xFFFF - Unused. If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. Note: The CANINT0 interrupt line remains active until INT0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. Reset type: SYSRSn

30.16.2.6 CAN_TEST Register (Offset (x8) = 28h, Offset (x16) = 14h) [reset = 0h]

CAN_TEST is shown in Figure 30-26 and described in Table 30-16.

Return to the Summary Table.

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

Note: Setting Tx[1:0] other than '00' will disturb message transfer.

Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

30.16.2.7 CAN_PERR Register (Offset (x8) = 38h, Offset (x16) = 1Ch) [reset = 100h]

CAN_PERR is shown in Figure 30-27 and described in Table 30-17.

Return to the Summary Table.

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism
it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

ABO_Time																															
R/W-0h																															

Table 30-22. CAN_ABOTR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ABO_Time	R/W	0h	Auto-Bus-On Timer Number of clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. "Clock" refers to the input clock to the CAN module. This function has to be enabled by setting bit ABO in CAN Control Register. The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO Time register after this phase. NOTE: On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted. NOTE: During Debug mode, running Auto-Bus-On timer will be paused. Reset type: SYSRSn

30.16.2.13 CAN_TXRQ_X Register (Offset (x8) = 108h, Offset (x16) = 84h) [reset = 0h]

CAN_TXRQ_X is shown in Figure 30-33 and described in Table 30-23.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN_TXRQ_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

3-2	TxRqstReg2	R	0h	Transmit Request Register 2 flag: Bit 2 represents byte 2 of CAN_TXRQ_21. If one or more bits in that byte are set, then bit 2 will be set. Bit 3 represents byte 3 of CAN_TXRQ_21 Register. If one or more bits in that byte are set, then bit 3 will be set. Reset type: SYSRSn
1-0	TxRqstReg1	R	0h	Transmit Request Register 1 flag: Bit 0 represents byte 0 of CAN_TXRQ_21 Register. If one or more bits in that byte are set, then bit 0 will be set. Bit 1 represents byte 1 of CAN_TXRQ_21 Register. If one or more bits in that byte are set, then bit 1 will be set. Reset type: SYSRSn

30.16.2.14 CAN_TXRQ_21 Register (Offset (x8) = 110h, Offset (x16) = 88h) [reset = 0h]

CAN_TXRQ_21 is shown in Figure 30-34 and described in Table 30-24.

Return to the Summary Table.

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

30.16.2.21 CAN_IP_MUX21 Register (Offset (x8) = 1B0h, Offset (x16) = D8h) [reset = 0h]

CAN_IP_MUX21 is shown in Figure 30-41 and described in Table 30-31.

Return to the Summary Table.

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

30.16.2.22 CAN_IF1CMD Register (Offset (x8) = 200h, Offset (x16) = 100h) [reset = 1h]

CAN_IF1CMD is shown in Figure 30-42 and described in Table 30-32.

Return to the Summary Table.

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

Note: This bit is write protected by Busy bit. Reset type: SYSRSn

30.16.2.24 CAN_IF1ARB Register (Offset (x8) = 210h, Offset (x16) = 108h) [reset = 0h]

CAN_IF1ARB is shown in Figure 30-44 and described in Table 30-34.

Return to the Summary Table.

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

30.16.2.25 CAN_IF1MCTL Register (Offset (x8) = 218h, Offset (x16) = 10Ch) [reset = 0h]

CAN_IF1MCTL is shown in Figure 30-45 and described in Table 30-35.

Return to the Summary Table.

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. This register has control/status bits pertaining to interrupts, acceptance mask, remote frames and FIFO option.

When the message handler stores a data frame, it will write the DLC to the value given by the received message. Note: This bit is write protected by Busy bit. Reset type: SYSRSn

30.16.2.26 CAN_IF1DATA Register (Offset (x8) = 220h, Offset (x16) = 110h) [reset = 0h]

CAN_IF1DATA is shown in Figure 30-46 and described in Table 30-36.

Return to the Summary Table.

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

30.16.2.28 CAN_IF2CMD Register (Offset (x8) = 240h, Offset (x16) = 120h) [reset = 1h]

CAN_IF2CMD is shown in Figure 30-48 and described in Table 30-38.

Return to the Summary Table.

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

Note: This bit is write protected by Busy bit. Reset type: SYSRSn

30.16.2.30 CAN_IF2ARB Register (Offset (x8) = 250h, Offset (x16) = 128h) [reset = 0h]

CAN_IF2ARB is shown in Figure 30-50 and described in Table 30-40.

Return to the Summary Table.

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

30.16.2.33 CAN_IF2DATB Register (Offset (x8) = 268h, Offset (x16) = 134h) [reset = 0h]

CAN_IF2DATB is shown in Figure 30-53 and described in Table 30-43.

Return to the Summary Table.

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

30.16.2.34 CAN_IF3OBS Register (Offset (x8) = 280h, Offset (x16) = 140h) [reset = 0h]

CAN_IF3OBS is shown in Figure 30-54 and described in Table 30-44.

Return to the Summary Table.

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

EtherCAT Slave Controller (ESC)

This chapter describes the implementation and integration of the EtherCAT Slave Controller (ESC). The ESC peripheral can be mapped to either CM or CPU1 subsystems (default access mapped to CPU1 subsystem), and thus either of these subsystems can run the EtherCAT slave stack and application software to implement an EtherCAT slave node.

On this device, the CPU1 is the master subsystem. If the intention is to use the CM subsystem as the owner of ESC, then certain ESC subsystem configurations can only be done by the CPU1 during initialization before allocating the ownership of the ESC peripheral to the CM subsystem. These details are explained in this chapter.

Information about the EtherCAT standards and working principles can be in found these documents.

- EtherCAT ET1100 Datasheet
- EtherCAT ESC Hardware Datasheet (Section I)
- EtherCAT IP Core for Xilinx FPGAs

Refer to EtherCAT IP Errata section for details on EtherCAT IP errata provided from Beckhoff Automation™.

Topic **Page**

31.1 Introduction

Ethernet for Control Automation Technology(EtherCAT) is an Ethernet-based fieldbus system, invented by Beckhoff Automation™ and is standardized in IEC 61158. All the slave nodes connected to the bus interpret, process, and modify the data addressed to them in progress, without having to buffer the frame inside the node.

The frames are directly forwarded with minimum additional delay. This real-time behavior, frame processing and forwarding requirements are implemented by the EtherCAT slave controller hardware. EtherCAT does not require software interaction for data transmission inside the slaves. EtherCAT only defines the MAC layer while the higher layer protocols and stack are implemented in software on the microcontrollers connected to the ESC.

A list of relevant terms and definitions as shown below.

Table 31-1. Abbreviations

Name	Definition
CM	Connectivity Manager (referring to Cortex-M4 subsystem on this MCU)
CPU1	Master C28 CPU1 subsystem on this MCU
EtherCAT™	Ethernet for Control Automation Technology
ESC	EtherCAT® Slave Controller
ESCSS or SS	Subsystem (specifically referring to EtherCAT Subsystem on this device)
SSC	EtherCAT Slave Stack Code
HAL	Hardware Abstraction Layer
PDI	Processor Data Interface
DIGIO	Digital IO profile
ET1100	Beckhoff EtherCAT slave controller
ETG	EtherCAT Technical Group
ESI	EtherCAT Slave Information
ENI	EtherCAT Network Information
FMMU	Fieldbus Memory Management Units
MII	Medium Independent Interface
POR	Power-on-Reset
XRS	External Reset
WDRS	Watchdog Reset
NMIWDRS	NMI Watchdog Reset

31.1.1 ESC Features

The ESC on this MCU provides the following functionality.

- Up to 2 MII ports to connect to EtherCAT PHYs
- 64-bit distributed clocking.
  - Sync output signals to synchronize device events and latch input signals supporting time stamping for events.
  - Distributed clock features of SYNC0/1 (o/ps) and LATCH0/1 able to synchronize GPIOs and allow inputs from any GPIOs as well as other muxing options for internal device events.
- 8 FMMUs
  - Supports all native types of RD/ WR/ RDWR and built-in features of bit/byte addressing
- 8 Sync Managers
- I2C EEPROM interface
- Up-to 32 general-purpose inputs and 32 General purpose outputs
- Process data interface through 16-bit asynchronous interface
- 2 SYNC and 2 LATCH signals connected to GPIO pads as well as critical signals internal to the chip

- 16 KB Process Data RAM with parity

31.1.2 ESC Subsystem Integrated Features

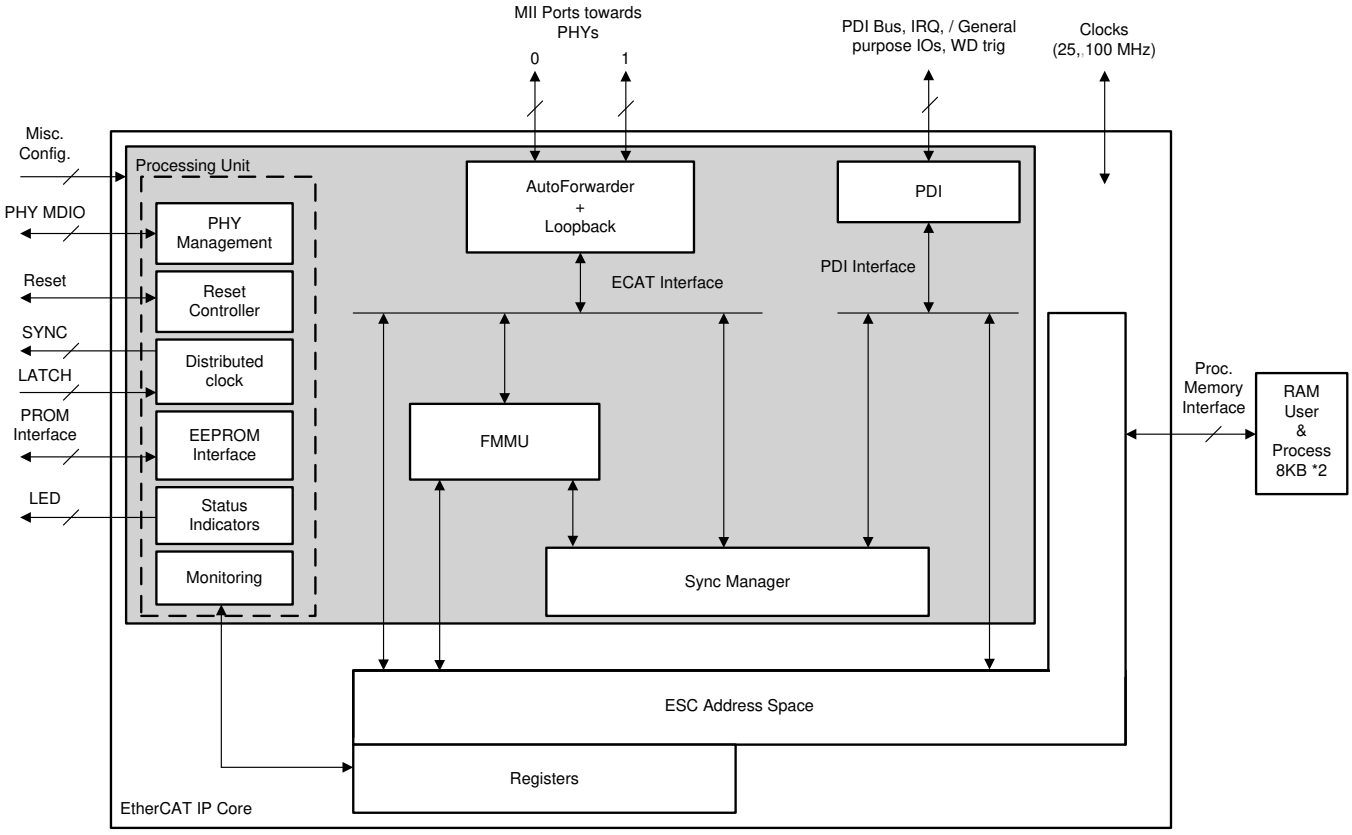
In addition to the ESC features, the following are the device-specific features provided by the integration of the ESC to the MCU:

- ESC access allocation to either CM (Cortex-M4) subsystem or CPU1 subsystem during initialization
- EtherCAT reset request from master can be routed to NMI or general Interrupt controller on MCU
- RAM Parity error routed to NMI on MCU
- DMA access to EtherCAT RAM
- Up to 32 GPI (general purpose inputs) and up to 32 GPO (general purpose outputs) feature integrated in addition to 16bit ASYNC PDI interface
- Interface to CLB
- Distributed clock feature of SYNC0/1 able to synchronize PWMs, generate interrupt/DMA requests, trigger ECAP capture, or allow external component action through GPIO access.
- EtherCAT SYNC0/1 pulse can trigger a CLA task.
- Distributed clock feature of LATCH0/1 allowing inputs from any GPIO or PWM crossbar triggers

31.1.3 EtherCAT IP Block Diagram

The block diagram shows the general functionality of etherCAT IP from Beckhoff and later on this chapter we will see how this is integrated into the MCU.

Figure 31-1. EtherCAT IP Block Diagram



31.1.4 ESC Functional Blocks

The description below introduces each of the sub-blocks. For more details, refer to the Beckhoff EtherCAT documentation.

31.1.4.1 Interface to EtherCAT Master

The EtherCAT master is a remote entity normally implemented through the device with ethernet switch capability. While Beckhoff suggests using either standard ethernet physical layer interface through MII or RMII protocol, or using low-voltage differential pair signaling with EBUS protocol, in this MCU implementation of ESC, user will have to use the Ethernet PHY interface through MII only. For this device implementation, it will only support 2 ports (a maximum of 4 can be supported as per Beckhoff specification) as there will be 2 MII ports connected at the device boundary.

31.1.4.2 Process Data Interface

Process data interface (PDI) is a connection from ESC to the micro-controller and slave application. The implementation of ESC on this MCU supports 16-bit asynchronous interface to local host; other interfaces are not supported.

31.1.4.3 General Purpose Inputs and Outputs

Digital IO type PDI with its generic nature allows splitting interface in local host communication and individual pin interface to other system components. As digital IO type PDI is not supported on this MCU, the discrete implementations which need independent IO controls may run in disadvantage. This is overcome by general purpose IO (up-to 32 GPI/GPO) support in addition to Async-16 bit PDI. EtherCAT GPI/GPO's can be programmed to either be driven by (or drive) device I/O pins or can be driven by (or drive) the same I/O pins after qualifying them using internal events. Refer toSection 31.2.9 for more details.

31.1.4.4 EtherCAT Processing Unit

The EtherCAT Processing Unit (EPU) receives, analyses and processes the EtherCAT data stream. It is logically located between port 0 and port 1. The main purpose of the EtherCAT Processing Unit is to enable and coordinate access to the internal registers and the memory space of the ESC, which can be addressed both from the EtherCAT master and from the local application via the PDI. Data exchange between master and slave application is comparable to a dual-ported memory (process memory), enhanced by special functions; for example, for consistency checking (SyncManager) and data mapping (FMMU). The EtherCAT Processing Units contain the main function blocks of EtherCAT slaves besides Auto-Forwarding, Loop-back function, and PDI.

31.1.4.4.1 Auto-Forwarder

The Auto-forwarder's functions included receiving EtherCAT frame, checksum computation and verification, timestamp capture for received frames, and forwarding to Loop-back component.

31.1.4.4.2 Loop-back Function

For the two-port implementation on this device, port 3 and port 2 are looped back by design, as shown in Figure 31-2. Port-0 is a special port that is always connected to the master while designing the topology. At egress it acts as a terminal point for network connected downstream, hence, any circulating packets shall get dropped at port-0 in event of Port-0 is looped-back. In event of a network or link loss downstream to the ESC port-1, the packets will end in loopback.

Figure 31-2. Two-port ESC description

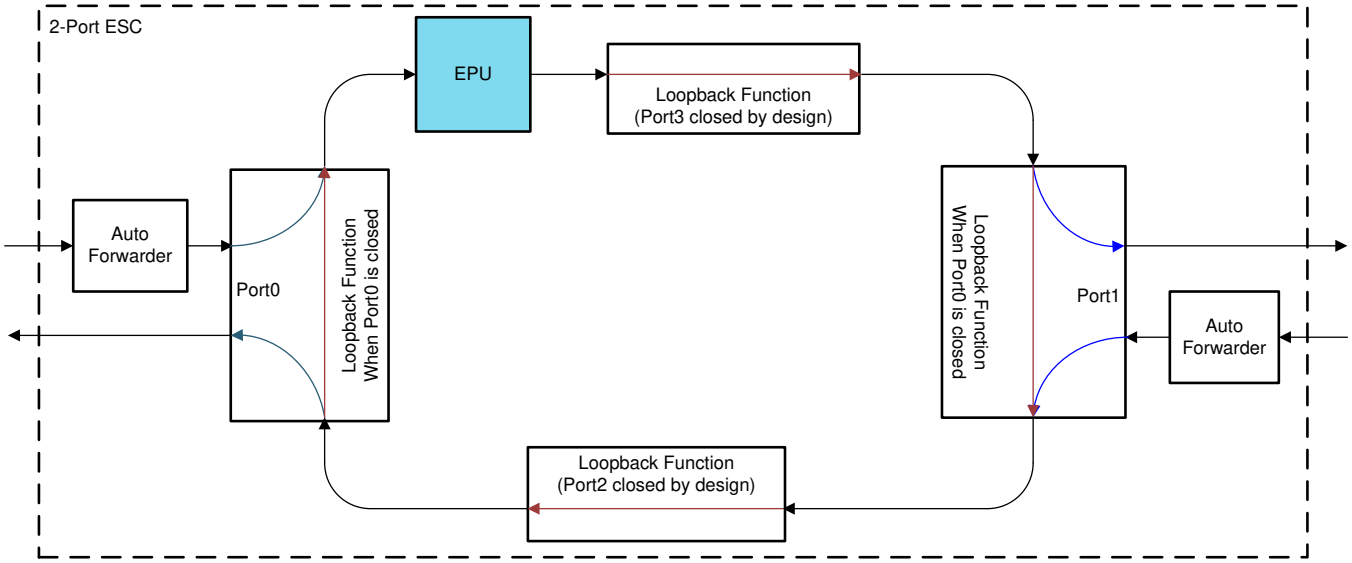


Figure 31-3. Two-port Block Diagram in EtherCAT Topology

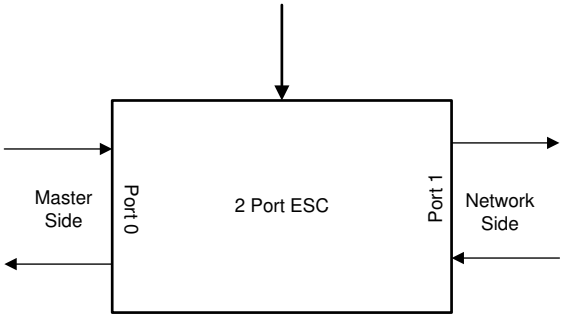


31.1.4.5 Fieldbus Memory Management Unit

The fieldbus memory management unit (FMMU) maps the logical addresses of the memory elements in ESC to physical address that allows the remote EtherCAT master to address registers and process ram as one memory map that can be accessed across the EtherCAT network. Mapping can be done up-to bit-wise mapping.

31.1.4.6 Sync Manager

The integrity and security of the data in dual port memory across Master & local application is maintained by the Sync Manager. Sync Manager allows data be accessed as buffered or mailbox, where either there is definite read/write space or sequence defined for both of the master entities.

31.1.4.7 Monitoring

The monitoring unit contains error counters and watchdogs. The watchdogs are used for observing communication and returning to a safe state in case of an error. Error counters are used for error detection and analysis.

31.1.4.8 Reset Controller

The reset controller aggregates the internal/external resets as well as asserts the reset to external pin, which can be connected to device pin to reset companion devices on the board.

31.1.4.9 PHY Management

The PHY control is maintained through the MDIO interface which allows the configuration of the PHYs and enabling advanced features of link detection if present be enabled.

31.1.4.10 Distributed Clock (DC)

Distributed clocks (DC) allows the tracked time at ESC be synchronized across the EtherCAT network, which in turn makes precisely timed event possible throughout the network. Events could be realized with triggers from ESC outputs which are programmed to create a toggle at certain absolute time tracked by the ESC or through sampling of timestamp of certain system event inputs to ESC which can further be used for synchronizing the time.

31.1.4.11 EEPROM

EtherCAT network needs non-volatile memory attached to every ESC, to store the configuration contents of the ESI (EtherCAT Slave Information) which are accessed by the Master normally before enabling the ESC in the network. This non-volatile memory is supported in simplest form by ESC IP core as serial access EEPROM. Size of the memory is configurable with a minimum of 1Kbit up to 4Mbit are supported depending on the ESC. This is supported using the I2C interface on this device and is further explained in Section 31.2.8.

Refer to the ESI and EtherCAT documentation from ETG and Beckhoff for ESI EEPROM Layout and mandatory information.

31.1.4.12 Status / LEDs

ESC supports the status indication of application activity, link status and link errors which can be utilized for visual status indication through LEDs.

31.1.5 EtherCAT Physical layer

EtherCAT slave devices with Ethernet Physical Layer usually support MII interfaces, while some do also support the RMII interface. Since RMII PHYs include TX FIFO's, they increase the packet forwarding delay of an EtherCAT slave device as well as the jitter. RMII as an Ethernet Physical Layer is not supported on this device due to these reasons and therefore only the MII interface is supported.

The following table depicts the number of pins needed for MII interface for two ports.

Table 31-2. EtherCAT Physical Layer Signals

Pin	Number of Pins for 2 Ports	MII	Direction	Description
nMII_Link	2	Yes	IN	Input signal provided by the PHY if a 100Mbits/s (full duplex) link is established
RX_CLK	2	Yes	IN	Receive Clock
RX_DV	2	Yes	IN	Receive Data valid
RX_DATA[1:0]	4	Yes	IN	Receive Data
RX_DATA[3:2]	4	Yes	IN	Receive Data
RX_ERR	2	Yes	IN	Receive error
TX_CLK(1)	2	Optional	IN	Transmit Clock
TX_ENA	2	Yes	OUT	Transmit Enable
TX_DATA[1:0]	4	Yes	OUT	Transmit Data
TX_DATA[3:2]	4	Yes	OUT	Transmit Data
MCLK	1	Yes	OUT	MII Interface clock
MDIO	1	Yes	BI-Directional	MII Interface Data

(1) The TX_CLK though optional with TX_SHIFT compensation, from the integration on this MCU point of view it is strongly recommended to route the TX_CLK port whenever the MII port interface is selected.

Table 31-2. EtherCAT Physical Layer Signals (continued)

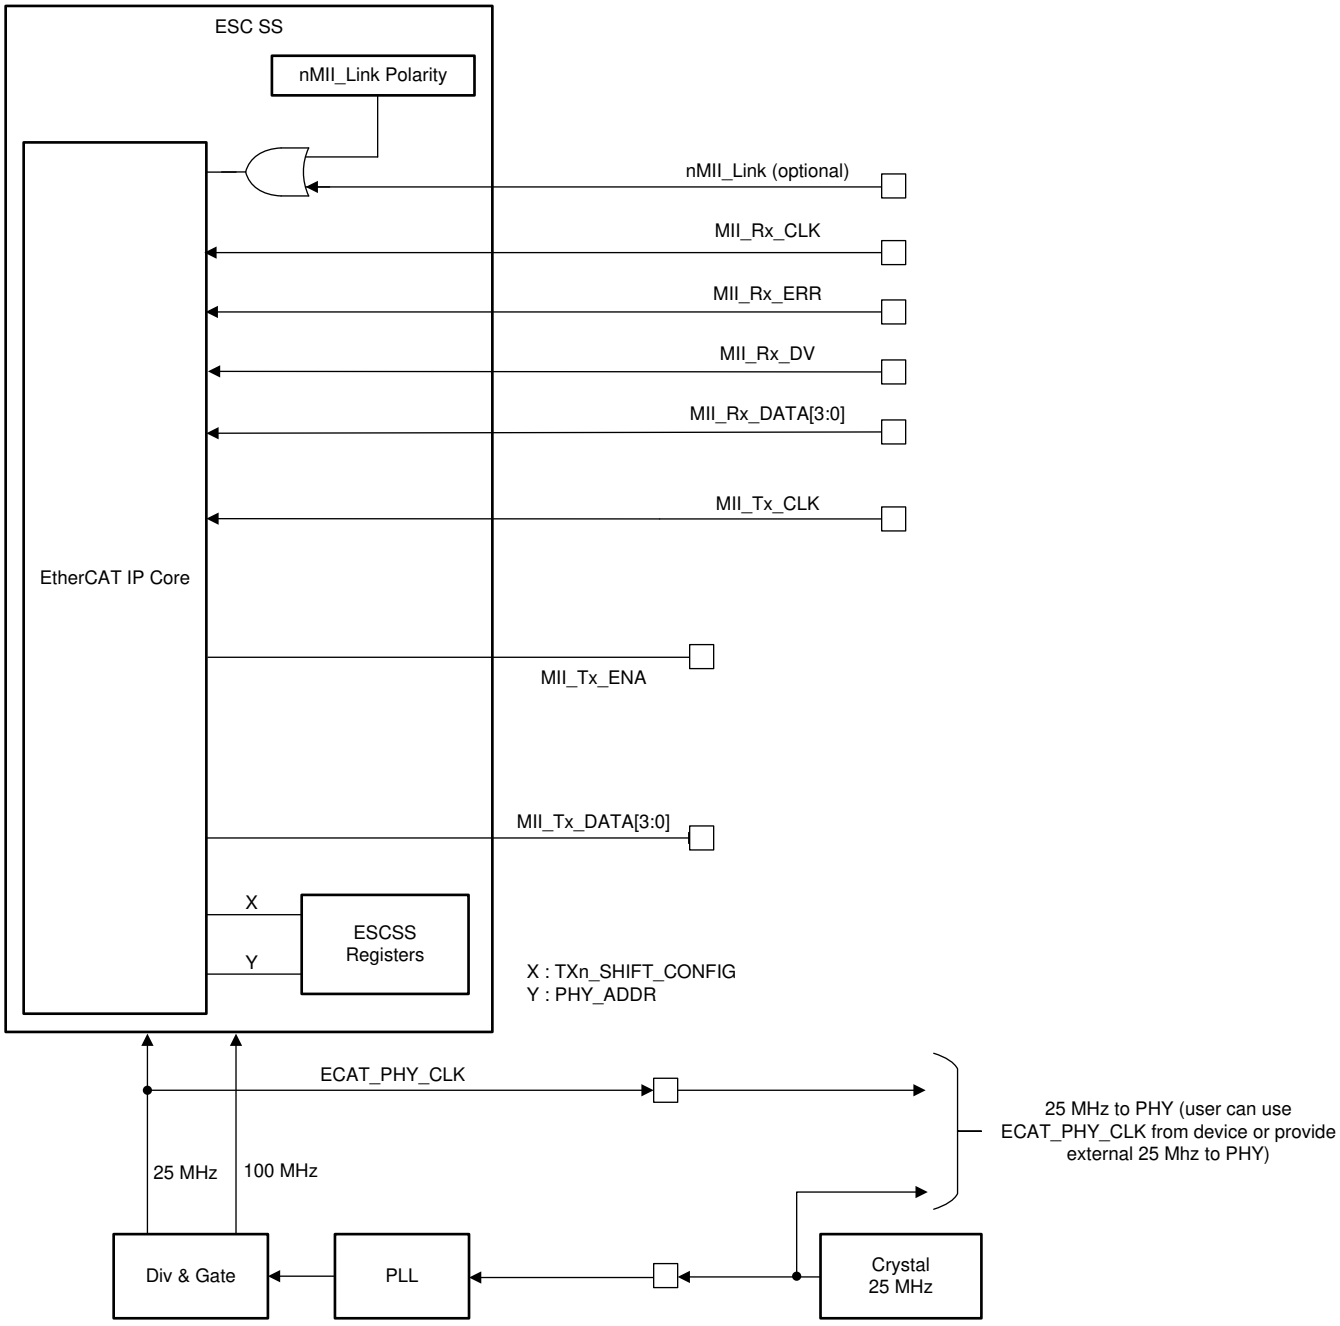
Pin	Number of Pins for 2 Ports	MII	Direction	Description
Total Pins:	28 (required) + 2 (optional)			

31.1.5.1 MII Interface

Ethernet IEEE802.3 specified MII interface is supported with possible minor variation in clocking to optimize the clock delay to operate the Tx FIFO. Unlike regular integration of Tx Clock being sourced by the PHY, the ESC implementation allows the common source clock between PHY and ESC be used for Tx logic. The option is selected by manual Tx shift compensation which allows Tx-Data and Tx-En be compensated in steps of 10ns to meet the timing requirements of data sampling at the PHY.

The following signals are used by the ESC to connect to an Ethernet PHY. The MDIO pins are not shown in Figure 31-4 as it is covered in next section.

Figure 31-4. ESC PHY Interface Diagram



(1) The PHY reset signal is also not shown in the above diagram.

The MII signals TX_ERR, COL and CRS are not used by the ESC. These are not available on the MCU for EtherCAT.

If an ESC MII interface is not used, LINK_MII has to be tied to the logic value high which indicates no link. RX_CLK, RXD, RX_ER, and especially RX_DV have to be tied to GND and this is taken care of by design internally when the functional IO mux for the RX pins is not configured when the IP is out of reset. The TX outputs can be left unconnected, by not configuring the Functional IO mux for respective EtherCAT functionality, unless they are used for ESC configuration.

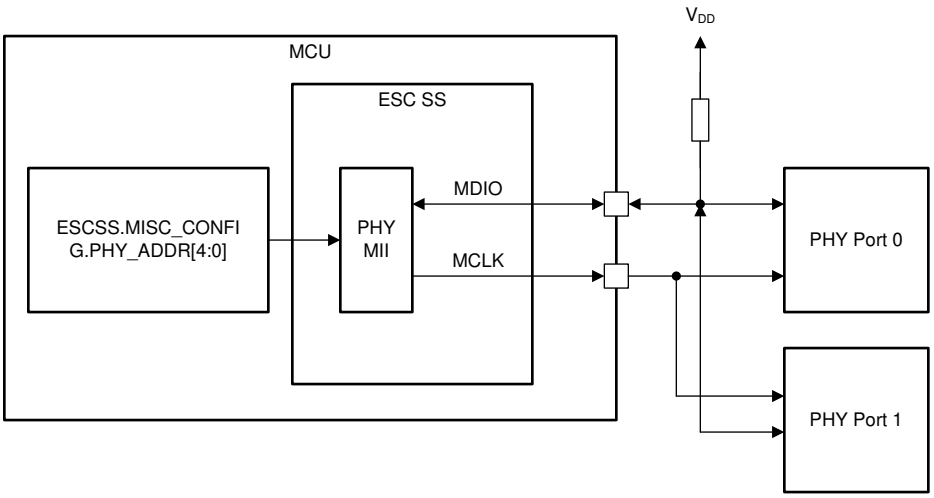
31.1.5.2 PHY Management Interface

Most EtherCAT slave controllers with MII/RMII ports use the MII management interface for communication with the Ethernet PHYs. Most ESCs do not use the management interface for link detection or configuration of link modes. For link detection, it is recommended that the ESC use a separate signal (LINK_MII). The MII management interface can be used by the EtherCAT master – or the local MCU. Enhanced MII link detection uses the management interface for restarting auto-negotiation after communication errors occurred.

On this ESC, it is possible to make use of the MII management interface for link detection and PHY configuration.

NOTE: Note that the EtherCAT link status through MII option should only be enabled if only a Gigabit PHY is to be supported and should not be enabled if needing to support both 10/100 and Gigabit PHY.

Figure 31-5. PHY Management Interface Connectivity



(1) Note that MDIO must have a pull-up resistor (4.7 kOhm recommended) externally. MCLK is driven rail-to-rail, idle value is High.

31.1.5.2.1 PHY Address Configuration

The ESC addresses the Ethernet PHYs typically using the logical port number plus the PHY address offset. Ideally, the Ethernet PHY addresses should correspond with the logical port number, so PHY addresses 0 and 1 are used.

A PHY address offset of 0 to 31 can be applied which moves the PHY addresses to any consecutive address range. The ESC module expects logical port 0 to have PHY address 0 plus the PHY address offset. The PHY address offset can be selected in register ESCSS_MISC_CONFIG.PHY_ADDR[4:0].

31.1.5.2.2 PHY Reset Signal

The PHY reset signal is generated out of the ESC module. If it is required to release both, the PHY and ESC module synchronous out of reset, this signal can be used. Since there are no pull devices active on the MCU during and after reset, a pull down resistor must be added on this signal on the board level.

In some case, PHYs may be released from reset after releasing the ESC module. To generate a delay, the pin for nPHY_RESET can be used as an I/O and shall be switched later to the alternate output function.

31.1.5.2.3 PHY Clock

The PHY Clock connectivity is shown in Figure 31-5. On this MCU, the user has option to clock the PHY using the ESCSS_PHY_CLK signal if needed otherwise user can chose to provide an external 25Mhz source to the PHY and ESC. For more details regarding providing PHY clock, refer to More Information on EtherCAT and see the EtherCAT datasheet from Beckhoff.

31.1.6 EtherCAT protocol

EtherCAT uses standard IEEE 802.3 Ethernet frames, thus a standard network controller can be used and no special hardware is required on master side. EtherCAT has a reserved EtherType of 0x88A4 that distinguishes it from other Ethernet frames. Thus, EtherCAT can run in parallel to other Ethernet protocols1. EtherCAT does not need the IP protocol, however it can be encapsulated in IP/UDP. The EtherCAT Slave Controller processes the frame in hardware, therefore, communication performance is independent from processor power.

An EtherCAT frame is subdivided into the EtherCAT frame header followed by one or more EtherCAT datagrams. At least one EtherCAT datagram has to be in the frame. Only EtherCAT frames with Type 1 in the EtherCAT Header are currently processed by the ESCs. The ESCs also support IEEE802.1Q VLAN Tags, although the VLAN Tag contents are not evaluated by the ESC.

If the minimum Ethernet frame size requirement is not fulfilled, padding bytes have to be added. Otherwise, the EtherCAT frame is exactly as large as the sum of all EtherCAT datagrams plus EtherCAT frame header.

For further reading on EtherCAT protocol refer to Section 1 Technology of the EtherCAT Slave Controller Hardware Data Sheet (ethercat_esc_datasheet_sec1_technology) available from Beckhoff and/or ETG websites.

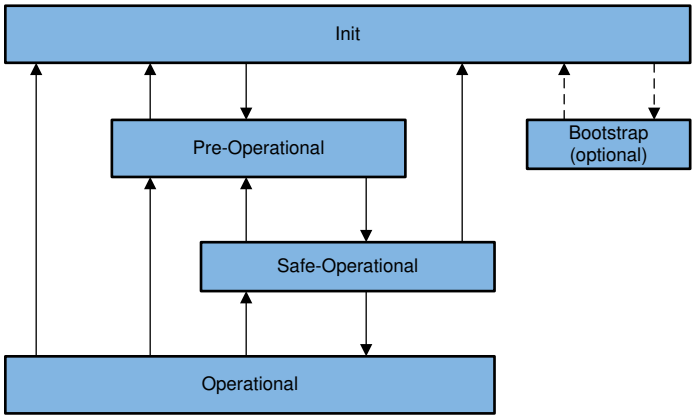
31.1.7 EtherCAT State Machine

The EtherCAT State Machine (ESM) is responsible for the coordination of master and slave applications at start up and during operation. State changes are typically initiated by requests of the master. They are acknowledged by the local application after the associated operations have been executed. Unsolicited state changes of the local application are also possible.

There are four states an EtherCAT slave shall support, plus one optional state:

- Init
- Pre-Operational
- Safe-Operational
- Operational
- Bootstrap (Optional)

Figure 31-6. EtherCAT State Machine



NOTE: Not all state changes are possible, for example, the transition from "Init" to "Operational" requires the following sequence: Init → Pre-Operational → Safe-Operational → Operational.

31.1.8 More Information on EtherCAT

For further information on EtherCAT, refer to the EtherCAT specification ETG.1000, available from the EtherCAT Technology Group (ETG, www.ethercat.org), and the IEC standard “Digital data communications for measurement and control – Fieldbus for use in industrial control systems”, IEC 61158 Type 12: EtherCAT, available from the IEC (www.iec.ch).

Documentation on Beckhoff Automation EtherCAT Slave Controllers are available at the Beckhoff website (www.beckhoff.com), for example, data sheets, application notes, and ASIC pinout configuration tools.

31.1.9 Beckhoff Automation™ EtherCAT IP Errata

The following details the Beckhoff Automation™ errata of the EtherCAT IP integrated onto this device.

Table 31-3. EtherCAT IP Errata

Errata Number	Description
ER#156	WKC increment for reading reserved FMMU registers (+0xD-+0xF)
ER#158	WKC increment for writing 0x0914-0x0917
ER#162	ESC DL Control (0x0101) loop setting Auto-Close (01): if port waits for write access to be opened, the temporary loop bit (0x0100[1]) is not taken into account when a write command to ESC DL Control occurs.
ER#164	EEPROM FSM cannot accept another command within 1680 ns after finishing a previous command
ER#165	EtherCAT reset register 0x0040 cannot be written using VLAN tagged frames, because state is reset due to double ECAT_CLEAR. VLAN tagged frames are rarely used for EtherCAT.
ER#168	Changing SyncSignal cycle times during activation can lead to extremely long cycle times, resulting from (intermediate) violation of the minimum delay between two consecutive pulses. E.g, changing Sync1 from a few ns before Sync0 to a few ns after Sync0 results in a missed Sync1 time, which could take up to several 32/64 bit turn-arounds until the next pulse occurs. Changing cycle time from PDI can result in usage of intermediate, inconsistent values, which could result in unwanted cycle times or extremely long delays as above.

31.2 ESC and ESCSS Description

This section details the aspects of the ESC integration in the MCU. On this MCU, the ESC is integrated such that the ESC peripheral can be accessed by either the CM subsystem or the CPU1 (master) subsystem. The MCU with the ESC will function as an EtherCAT slave device.

Figure 31-7 shows the ESC on this MCU.

Figure 31-7. ESC Integration on MCU

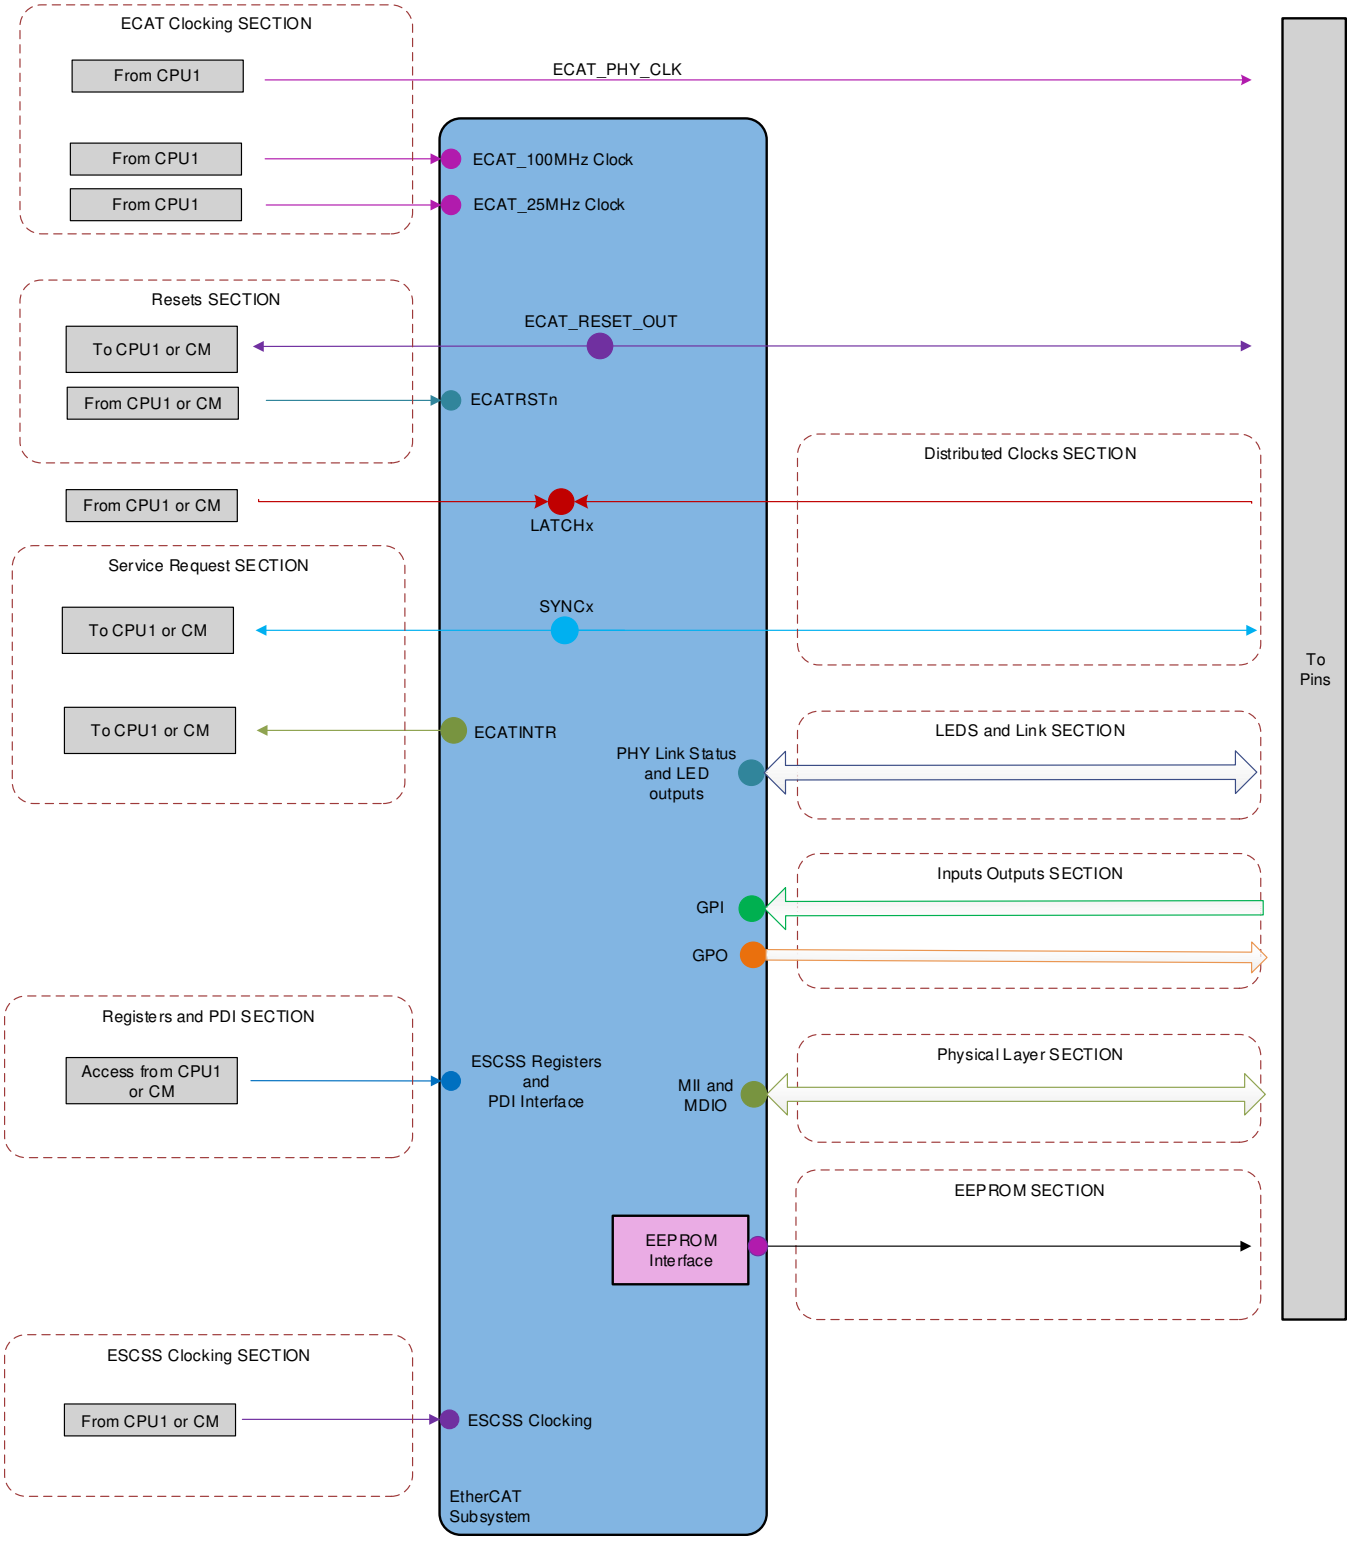


Table 31-4. ESC Integration Figure Sections

ESC Figure Sections	More Information Links
ECAT Clocking	ESC Clocking

Distributed Clocks	Distributed Clocks - Sync and Latch Integration
LEDS and Link	LED Controls
Inputs Outputs	General Purpose Inputs and Outputs
Physical Layer	EtherCAT Physical Layer
EEPROM	Slave Node Configuration and EEPROM

There are various actions that the controlling processor (CPU1/CM) needs to perform in response to actions initiated by the EtherCAT Master meant for this particular slave. All these interactions take place through one of the following:

- The 16-bit Asynchronous interface through which registers and RAM of the EtherCAT IP are read/written.
- An interrupt request going from the ESC to the Local Host (CM or CPU1).
- SYNC0 and SYNC1 pulses generated by the ESC which can be used as triggers for initiating further action.
- LATCH0 and LATCH1 which will be sampled by the ESC.
- EtherCAT general purpose inputs and outputs.

31.2.1 ESC RAM Memory Maps

This section details the CPU1 and CM ESC memory maps.

31.2.1.1 CPU1 ESC RAM Address Map

When the ESC is allocated to CPU1, below is the memory map and associated details.

Table 31-5. ESC SS Address Map On CPU1

Memory Map Region	Memory Region	Accessed through	Parity scheme	DMA Access	CLA Access	CPU2 Access	Security	Access/Bus
DPRAM memory map (16 KB)	0x00050800 - 0x000527FF	PDI interface of ESC	1 parity bit for 8 bits of data.	Yes[1]	No	No	No	Async
ESC Registers	0x00050000 - 0x000507FF	PDI Interface of ESC	No	No	No	No	No	Async
ESCSS Registers	0x00057E00 - 0x00057FFF	Direct Access	No	No	No	No	No	VBUS32

(1) The CPU1 DMA access is only available to the lower 4KB of the ESC RAM memory map. This memory region is 0x52000 to 0x527FF.

31.2.1.2 CM ESC RAM Address Map

When ESC is allocated to CM, below is the memory map and features.

Table 31-6. ESC Address Map on CM

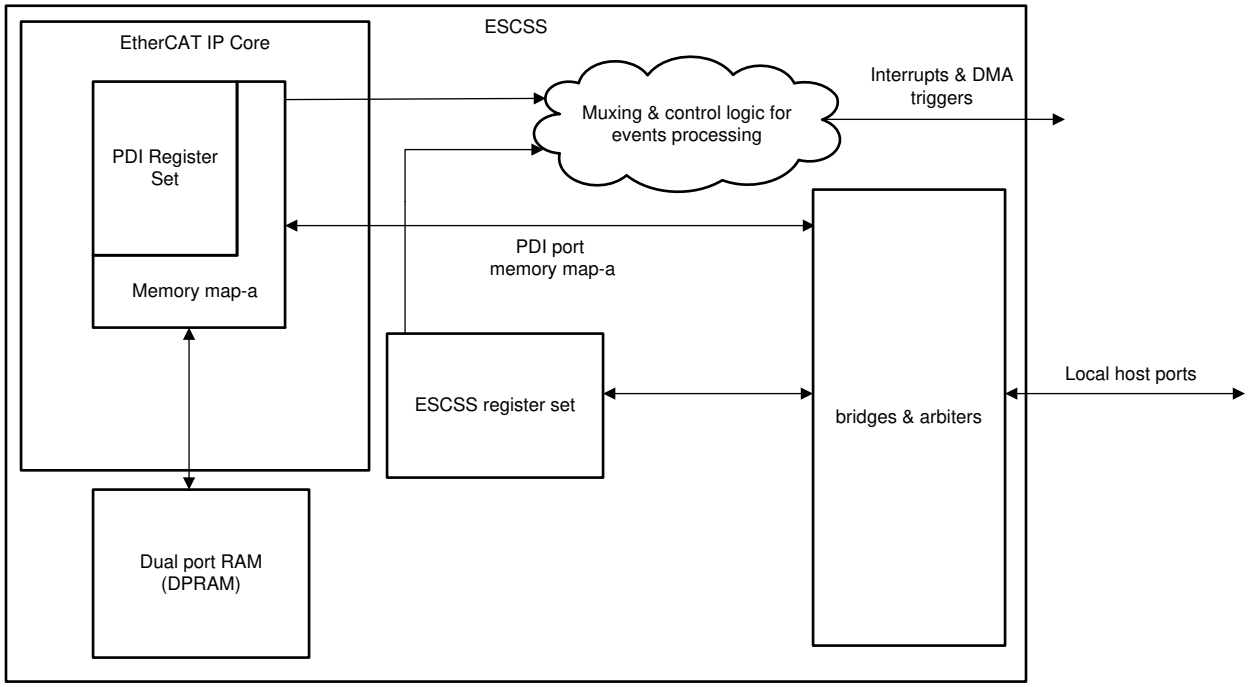
Memory Map Region	Memory Region	Accessed through	Parity scheme	uDMA Access	Bus/Protocol	Security
ESC RAM memory map (16 KB)	0x400A1000 - 0x400A4FFF	PDI interface of ESC	1 parity bit for 8 bits of data.	Yes	System/PDI	No
ESC Registers	0x400A0000 – 0x400A0FFF	PDI	No	No	System/PDI	No
ESC_SS Registers	0x400AFC00 – 0x400AFFFF	Direct Access	No	No	System/VBUSP	No

31.2.2 Local Host Communication Ports

Figure 31-8 shows how the ESC and ESC subsystem connects to the Local host subsystem. Local host subsystem can include the CPU (CPU1 or CM) of the device and DMA engine as bus masters accessing the EtherCAT IP. This local host subsystem will be acting upon the commands which are sent to it by the EtherCAT Master in the form of EtherCAT datagrams.

The 16-bit Asynchronous interface and the interrupt request line are the main channels through which the Local host subsystem interacts with the EtherCAT IP. The interrupt request line can be used to trigger actions based on EtherCAT IP internal events, exception conditions or time synchronized events. DMA engine is used to transfer the contents from the process data memory to system RAM on any of these events. The user application needs to select the events that will act as interrupts or DMA requests. The mask and clear events for the interrupt causes are configured to be accessed by the CPU/Co-processor that is mastering the EtherCAT IP.

Figure 31-8. Interaction of ESCSS with the CPU Subsystem



31.2.2.1 Byte accessibility through PDI

The ESC has a few registers which need byte wide access to affect the functionality. The EtherCAT implementation on this MCU does not support the byte accessibility for CPU1 but supports byte accesses from CM. All register accesses through CPU1 will be 16 bit accesses.

31.2.2.2 Parity Logic Implementation

The ESC RAM has Parity logic to ensure the data integrity of the contents. The byte wide parity is implemented as PDI accesses to RAM could be done byte wide. To ensure that errors in parity logic itself do not mask the memory error, redundant parity generation logic will be used. The parity generated by both logics is compared to ensure safe operation of the memory accesses. Use MEMINIT bit from the ESCSS register to trigger the memory initialization.

31.2.2.3 Software Details for Operation Across Clock Domains

The registers accessible from the CPU would be in the system clock domain and hence those will be synchronized to the PDI clock before being used within the EtherCAT IP. Given the frequency ratios and different styles of synchronisation schemes, the application needs to assume there's a delay in getting the values transferred from one domain to other. Such a delay could vary based on the frequency of system clock and/or type of synchronizer used in the path. For example, a system clock of 200MHz and ESCSS running at 100MHz would require at least 10 clock system clock cycles delay before values are affected on the other side. If a write occurs to the PDI and some other action is performed elsewhere (not involving the PDI) then the software should perform a simple read to ensure that the write is complete.

31.2.3 Debug Emulation Mode Operation

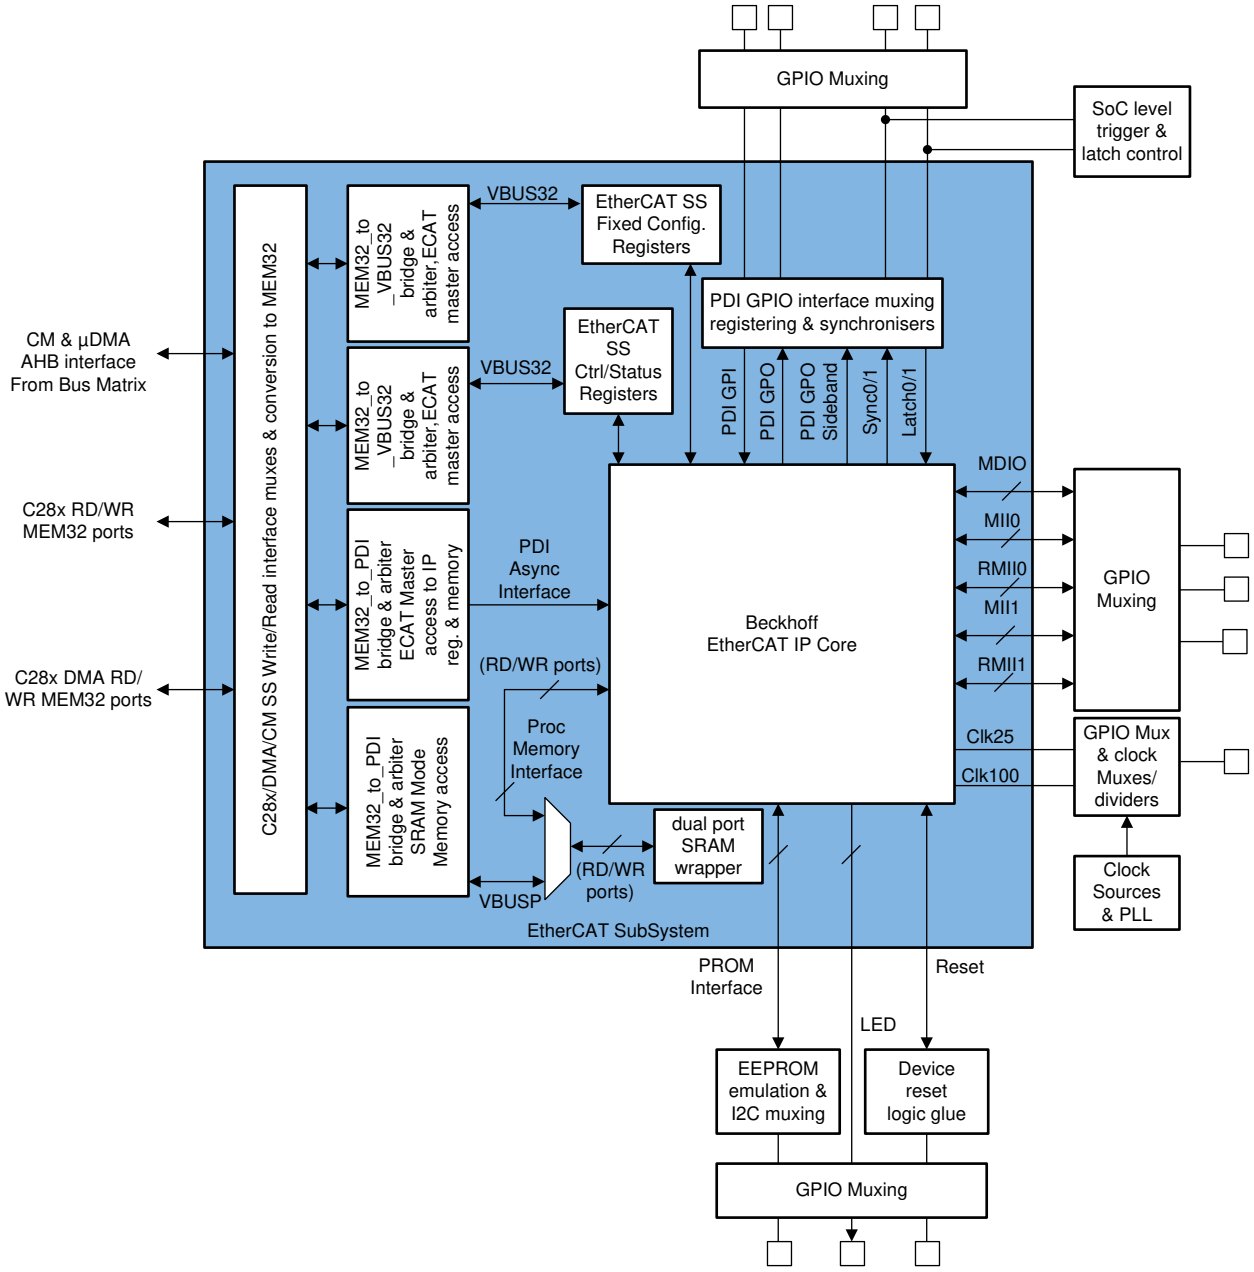
There are two aspects of the EtherCAT IP operation that need to be considered from an emulation stand point.

- CPU Halted condition (Applicable only for CPU1): For any operation from the EtherCAT IP which is based off an interrupt request, it is quite important that this interrupt is marked as a realtime interrupt and the debugger must be halted in RealTime mode. If the CPU is halted without taking the above precaution, then the EtherCAT IP can only be active for those parts where servicing the interrupt is not required (For example, GPIO and SYNC0/1 output triggers can all function unaffected).
  - As CM does not have the concept of Real time debug, it will remain in Halt mode until released by the run command again regardless of interrupt request assertions.
- Debugger reads of EtherCAT IP registers and memories (applicable to both CPU1 and CM accesses): The EtherCAT IP does not have any mechanism to identify a debug initiated read/write. Debug accesses to the registers or the Dual Port RAM can affect the state of the EtherCAT IP. The issue is addressed by the following.
  - By default, the VBUS bridge will gate off any debug related access to the EtherCAT address space. A special enable bit has to be set in order to allow debug accesses to the EtherCAT IP. This is to enable the user for deliberate access to the ESC RAM and EtherCAT registers purely for the purpose of debug. This bit is OFF by default. In this state, debug writes will be ignored and debug reads will return a value of 0.

31.2.4 ESC SubSystem

The EtherCAT Slave Controller SubSystem (ESCSS) wraps the ESC core with required register configurations and required logic for different functions of the EtherCAT and RAM (ESC RAM). This section covers the ESCSS integration aspects. Figure 31-9 below shows the EtherCAT subsystem Integration.

Figure 31-9. ESCSS Wrapper



31.2.4.1 Bus Interfaces

The ESCSS has four bus masters and three slave entities which require efficient arbitration and lossless protocol conversion across the bridges. A Local host (CPU) subsystem including one or many bus masters could connect with EtherCAT at any given instance.

- ESCSS Configuration registers slave interface is the port for accessing the critical device level configurations which are a must have for the ESCSS to function. This port is accessible to both CPU1 and CM as master.
- ESCSS register slave interface has control and status registers including SYNC, LATCH configurations, interrupt related controls, and GPI/GPO related controls. These controls are expected to be exercised by the bus master as selected out of the reset. Note this interface is accessible to CPU1 to begin with at power on or ecatXRSn reset and later only one master as selected in device system control for this IP is statically muxed on this slave port.

- PDI Async slave interface is a 16 bit wide data interface that allows the local application to access the registers internal to the EtherCAT IP Core as well as the dual port memory through the SyncManager and the FMMUs. This slave has a native Async Interface that can be selected through PDI configuration.

31.2.4.1.1 CPU1 Bus Interface

Interface to the CPU1 core is retained at the ESCSS boundary as a native mem32 interface which connects the RD and WR ports independently to all the slave entities within the ESCSS.

- CPU1 MEM32 RD/WR ports are: Config. Registers, Control/Status Registers, PDI

31.2.4.1.2 CM Bus Interface

The CM interface involves the AHBLite bus that is arbitrated between CPU and uDMA accesses to PDI. While the same bus connects to the register space, the bus-matrix address decode does not allow uDMA to access the register space.

- CM System bus ports->Config. Registers, Control/Status Registers, PDI
- uDMA ports->PDI

31.2.5 Service Request Generation

The ESCSS has different types of sideband and control signals including interrupts, DMA triggers, and status LEDs.

31.2.5.1 Interrupts and Interrupt Mapping

The ESC has one interrupt line that can be connected to the local host this is called PDI IRQ from the ESC. Besides this, there are other interrupt causes generated within the ESCSS. These are aggregated to a total of 4 interrupt lines that are connected to local host core. Note that local host refers to a set of masters or a master that has access to the bus interface of ESCSS and it can access the register space of the subsystem and PDI interface.

Table 31-7 below summarizes these exceptions and their mapping. Each of these causes have an independent set of mask/clear/set controls and raw/masked interrupt status flags.

This allows independent cause servicing on the exception event with flexibility to mask or service the desired set of causes. The DMA_DONE cause is specific to uDMA integration in the systems and it is routed to the CPU that is master of the EtherCAT. While uDMA configuration will be limited by the CM core, in cases where uDMA request is linked to time precise SYNC triggers, the EtherCAT master should be able to clear the DMA_DONE RIS (RAW Interrupt Status) to re-arm the uDMA request generation in ESCSS. If unused, this interrupt cause should be kept masked by the EtherCAT master CPU.

In event that the same exception is available to the multiple bus master cores of the local host CPU then it is expected that the application software ensures clearing of the RIS is a software synchronized event between those masters and there is no stale exceptions pending for one master while the other clears the RIS. In other words, there is no separate exception cause (RIS/MIS) copy per master but are common interrupt registers for the local host across masters.

Table 31-7. Service Request Generation Map

Source	Description	Master				
		CPU1	CLA	CPU1 DMA	CM	uDMA
EtherCAT IRQ	AL Event Request of the ESC	ECATSS_intr	ECATSS_intr	Not Available	ECATSS_intr	Not Available
PDI Interface Timeout Error	PDI Interface WatchDog timeout error	ECATSS_intr	ECATSS_intr	Not Available	ECATSS_intr	Not Available
uDMA Done(1)	This event indicates to CM or CPU1 that uDMA transfer by earlier event is over	ECATSS_intr	Not Available	Not Available	ECATSS_intr	Not Available

(1) Only uDMA has the DMA_DONE qualifier. This is not applicable to the CPU1 DMA.

Table 31-7. Service Request Generation Map (continued)

Source	Description	Master				
EtherCAT RESET_OUT Event	RESET_OUT can be programmed as interrupt to the CPU to either complete the reset sequence with required pre-steps if an or acknowledge the reset request in some other way. Given the high priority nature of the signal independent interrupt line is allocated	RESET_OUT_Intr	RESET_OUT_Intr	Not Available	RESET_OUT_Intr	Not Available
SYNC0 Event	Precise time event 2, can be used to start routine SYNC1_Intron cores or data transfer using DMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC0_Intr	SYNC0_Intr	SYNC_DMAReq	SYNC0_Intr	SYNC_DMAReq
SYNC1 Event	Precise time event 1, can be used to start routine on cores or data transfer using DMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC1_Intr	SYNC1_Intr	SYNC_DMAReq	SYNC1_Intr	SYNC_DMAReq

As seen in Table 31-7 above, there are 4 interrupt lines provided for ESCSS which are: ECATSS_Intr, RESET_OUT_Intr, SYNC0_Intr and SYNC1_Intr. All these interrupts are mapped onto NVIC on CM and PIE on CPU1. Please refer to the System Control chapter of the TRM for details on the interrupt numbers.

31.2.6 Power, Clocks, and Resets

This section details the ESCSS power requirements, clocking, and resets. The EtherCAT IP has 2 clock ports and one reset output. The PLLs, dividers, and gating is implemented in common (System control) logic and are set up by the master CPU1 during the initialization sequence.

31.2.6.1 Power

The ESC module is inside the main power domain like other peripherals and there are no special considerations about power up or power down sequences that need to be taken. Please refer to system control chapter for different power modes.

31.2.6.2 Clocking

Two functional clock inputs are defined for the ESC which are CLK25 (25 Mhz) and CLK100 (100 Mhz). Additionally, besides CLK25/CLK100, there is a bus clock connected to the ESCSS which drives the register interface.

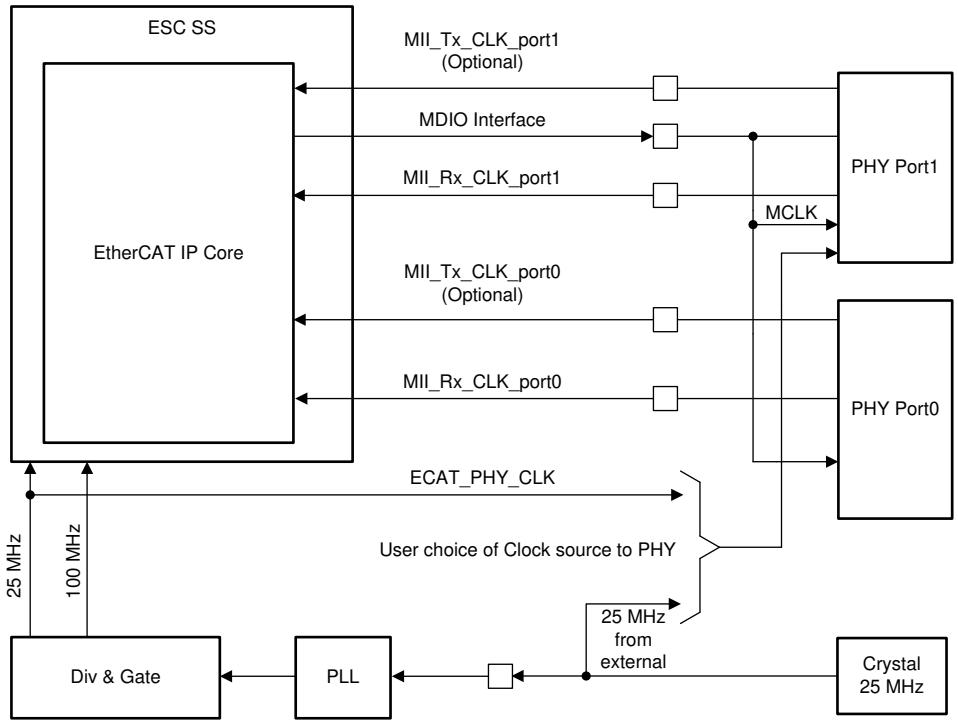
31.2.6.2.1 Functional Clock

EtherCAT functional clock inputs CLK25 and CLK100 are sourced by the MCU clocking module either using SYSPLL or AUXPLL. At the SoC level, a user has multiple options to choose from regarding what inputs are used for the SYSPLL or AUXPLL but because of the stringent PPM requirements of EtherCAT, an external crystal of 25MHz is suggested to be used as the main clock source.

CLK25 and CLK100 are used for the ESC core operation. These two clocks and the clocks to the PHY must have a common source, which establishes a deterministic phase relationship between PHY clocks and ESC clocks. In MII mode, 25MHz RX clock is sourced by the PHY while the TX clock from PHY is optional which effectively saves a pin. The phase differential between the PHY TX clock and CLK25 can be compensated to the TX data and TX EN using the manual compensation mode in increments of 10ns.

Figure 31-10 shows the clocks connectivity. Additional details of the PLL source selections and clock dividers are explained as part of the system control chapter.

Figure 31-10. Clocking of ESC



As it may not be always feasible to have a clock accuracy of 25ppm, in the case of a low accuracy (up to 100ppm) clock being used then the following restrictions apply:

- RX FIFO size can not be reduced lower than 7 (Default for 100ppm) which in turn affects the latency of transfer as transfer starts after half of FIFO full threshold, thus resulting in a RX Delay.
- This ECS cannot be used as first slave from master, as typically first slave from master is treated as the reference clock of DC.
- The number of iterations required for synchronizing clocks (specially the drift computation) increases.

31.2.6.2.2 Bus Clock

The ESCSS is connected on the system buses and interacts with the master CPU1 and/or local host in after reset and operational phases. Out of reset the master CPU controls the device configuration settings of the IPs like IO control, IO mux selection, in this phase it connects to the system clock of master CPU. While when the local host for the ESCSS is assigned, the corresponding CPU's system clock drives the ESCSS register interface.

31.2.6.2.3 Clock Un-gating and Reset Release Synchronization Delay

The ESCSS supports asynchronous clocking with respect to the system clock, which controls some of the clock control and reset control registers in the system control of the device. The ESCSS registers, either the configuration or control/Status, are all asynchronous however the EtherCAT IP core (with functional clocks) could have synchronous reset flops. Thus before EtherCAT IP Core reset release, it is expected to have at least 3 clock cycles of the slowest functional clock that is 25MHz(40ns) and it is recommended to introduce a delay of 120ns effected in terms of the system clock

31.2.6.3 Reset

This section describes the ESCSS sources of reset. There are other conditional reset sources which may impact ESCSS and those include all the device level reset sources including: device pin reset "XRSN" or software initiated device level reset "SYSRSn".

NOTE: Whenever the device comes out of reset, software must execute the following sequence to ensure that PHY can see the full stretching of its reset:

1. Configure the EtherCAT GPIOs
2. Put the ESCSS into soft reset
3. Bring the ESCSS out of soft reset

Refer to Software Initialization Sequence more information on proper software procedure.

31.2.6.3.1 Chip Level Reset

Chip level resets (such as POR, XRS, WDRS, or NMIWDRS) is a master reset that resets the entire device including EtherCAT IP.

31.2.6.3.2 EtherCAT Soft Resets

ESCSS can be reset by three soft reset mechanisms, including:

- System control level software programmable (SOFTPRES23) which is reset only by chip level and EtherCAT resets. Default keeps the IP in reset which is released by local application after setting EtherCAT ready for operation.
- Reset by a particular command sequence from Remote EtherCAT master.
- Reset by a particular command sequence from the local host application. (CM core only)

31.2.6.3.3 Reset Out (RESET_OUT)

Multiple reset sources of ESCSS are combined to make the reset vector that drives the EtherCAT and companion devices (PHYs) on the board. The RESET_OUT is asserted only when it is configured to be a reset and if configured as interrupt or NMI, it is expected that the local host will complete the reset.

By default, RESET_OUT performs no action and must be setup to cause the reset to IP core and PHY. The input events to RESET_OUT include the remote EtherCAT Master, local host application, and EtherCAT soft reset.

When the intent is to perform a reset to the ESCSS and the device, the following options are available to reset the device after software has given a reset to the ESCSS:

- Use the system control SIMRESET register to generate a device reset.
- Use the watchdog or NMIWD to generate a device reset.

31.2.7 LED Controls

There are four LED outputs from the ESC which can be routed out of GPIO to indicate different statuses of the ESC. The following is the recommendation for applications on the usage specially for the pin sensitive systems which can support this and still meet the intent. All the LED functions are routed to the peripheral pin mux and it is up to the user to configure the LEDs as per the available pins.

Table 31-8. Status LED Options and Priority

LED	Priority Order	Function	Recommendation	Usage priority
RUN	5	Shows the status of ESC state machine with different blinking patterns	When no Color LED and separate status or State & Error can be reported then this can be supported.	Must
ERR(1)	4	Indicates the Error in ESC operation.	In case color LEDs are not supported then at least the Error status needs to be reported.	Must
STATE	2	Combination of the RUN & ERR LED	Not supported on this device.	-

(1) Driven by software, not ESC IP on this device.

Table 31-8. Status LED Options and Priority (continued)

LED	Priority Order	Function	Recommendation	Usage priority
LINKACT0	3	Link Active Status for link towards Master.	Link Status on Master side (Port0) is important to know if the ESC and network downstream is part of network or not the prior ESC will loopback if this node fails hence frame would reach, Status on LED eases the debug.	Desired
LINKACT1	1	Link Active status for link towards Network side.	The Link status on the network side (Port 1) is critical from continuity through the ESC point hence this is kept highest priority status reporting.	Must

The PHY MII_LINK indication is gross indication from PHY and may not really indicate if the established link meets the characteristics including auto-negotiation as required by EtherCAT. Hence it may not be true status indication, however, it is critical to shorten reaction time in the event of link loss which is crucial for redundancy operation. Using LINKACT LEDs for the status output and MII_LINK for the status input is the most ideal usage, however, they may not be practical to sacrifice 4 pins, hence the tradeoff of whether MII_LINK itself is used as crude Link status LED or LINKACT is used depends on link loss reaction time requirements and available number of GPIOs for the system.

NOTE: Note that the EtherCAT link status through MII option should only be enabled if only a Gigabit PHY is to be supported and should not be enabled if needing to support both 10/100 and Gigabit PHY.

31.2.8 Slave Node Configuration and EEPROM

The ESC hardware configuration is stored in non-volatile memory (e.g. an EEPROM), the Slave Information Interface (SII), which contains information about the basic device features, so that the master can read this at boot-up and operate the device even if the device description file is not available at the master. The EtherCAT Slave Information (ESI) file that comes with the device is XML based and contains the complete description of its network accessible properties, such as process data and their mapping options, the supported mailbox protocols including optional features, as well as the supported modes of synchronization.

31.2.9 General Purpose Inputs and Outputs

The ESC subsystem implementation on this MCU supports 32 General Purpose Inputs and 32 General Purpose Outputs in addition to the PDI. These GPI/GPOs provide an advantage for embedded applications over discrete components in that they can selectively drive or sense GPIOs in a time controlled manner. General purpose inputs and outputs are supported with EtherCAT IP Core to allow individual I or O functions either acting as "input from" or "output to" companion hardware in system. For example, it could be a sensor/actuator control or status read or LED status update, etc. The section below describes the integration scheme and usage of this feature.

31.2.9.1 General purpose inputs

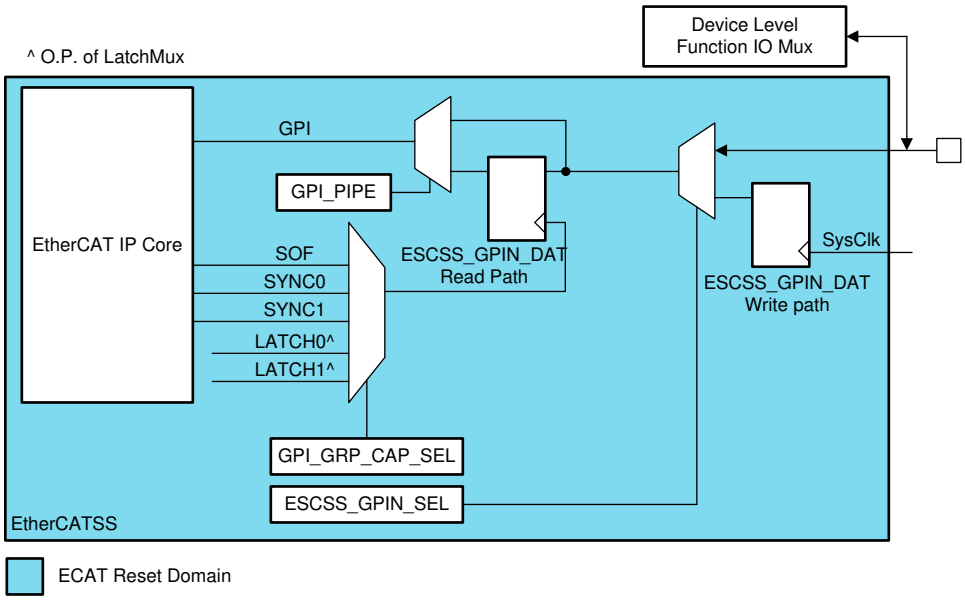
General purpose inputs shall be connected to the GPIO PAD through an input buffer with an option to directly connect the asynchronous input flowing into the IP or through a ESCSS register pipeline. The state of the input pad can be registered based on Start of Frame such that contents are ready for capture in the frame if requested by remote master. Alternatively, it could be setup for latching the GPI states on a precise time tick as given by SYNC0/SYNC1 or synchronized GPI read with LATCHIN (selected to be either LATCH0 or LATCH1).

Usage with LATCHIN would allow simultaneous input and timestamp capture. This MCU implementation allows both the direct input from IO or pipelined(registered) input which can in-fact hold the value stable while it is captured within ESC.

The copy of the pipelined stage is made readable from the local host through ESCSS_GPIN_DAT, hence allowing the debug access or in certain cases, if need be, emulate the GPI functionality when enough number of IO pads are not available. ESCSS_GPIN_DAT is therefore a R/W register which has synchronized access from SysClk domain. Note that when doing a CPU read of the ESCSS_GPIN_DAT register, multiple reads must be performed by the CPU in order to confirm a stable value in the register before using it.

Figure 31-11 below illustrates integration of the GPI feature.

Figure 31-11. ESC SS General Purpose Inputs Integration



NOTE: For Software: The write data will get reflected on the ESCSS_GPIN_DAT read path only when one of the configured events like SOF, SYNC0/1, etc is seen as configured after a few cycles of that event getting generated. Additionally, the copy of ESCSS_GPIN_DAT register readable by the CPU is provided without synchronization, therefore multiple reads should be performed to confirm a stable value before using it.

GPIs are divided in 4 sets of GPI0:7, GPI8:15, GPI16:23, and GPI24:31 for clocking the capture trigger, which means the same capture trigger has to be used for the IOs within a set. Thus either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs while keeping the complexity low. As usage of all 32 GPIs and GPOs is unlikely, the implementation offers porting of application which is using such implementations. Selection of which Inputs (ESCSS_GPIN_SEL) and outputs (ESCSS_GPOUT_SEL) can be connected to GPIO is possible at each single IO level.

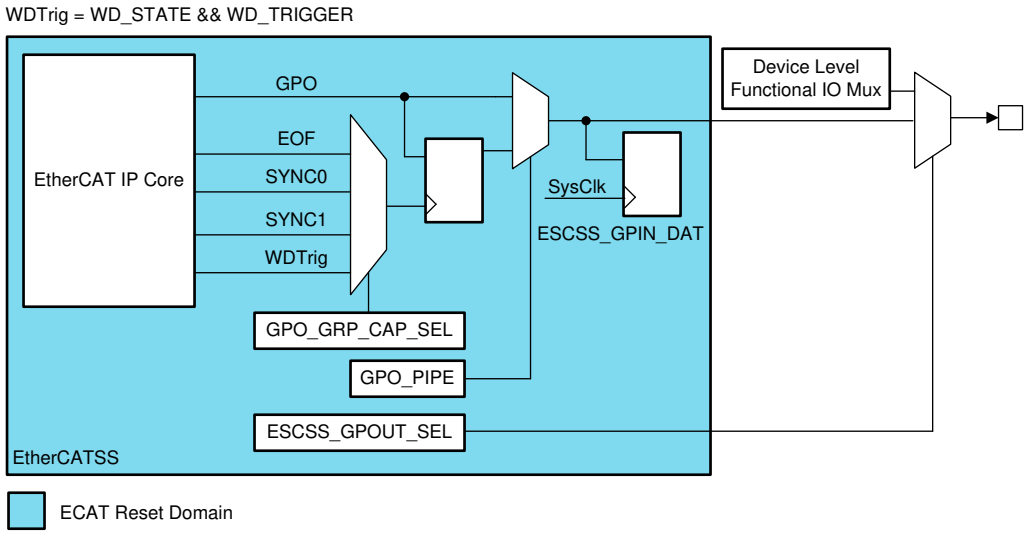
31.2.9.2 General Purpose Output

General purpose output can be connected to IO-pad and output buffer directly from the ESC IP core registers making internal toggles transparent to external world or by using the pipelined register. The pipelined register is captured from the EtherCAT IP source upon end of frame so that the Output updated by EtherCAT master in the last frame is updated. Additionally, a time synchronized GP output value can be captured based on SYNC0/SYNC1 or based on the last successful access to process data memory. The output value can be held stable until the next trigger update if pipelined output is used. A copy of the pipeline register (ESCSS_GPOUT_DAT) is made readable from local host in case there is scarcity of the IO pads.

Finally, simplification of trigger programmability is limited between a set of GPOs namely GPO0:7, GPO8:15, GPO16:23 and GPO24:31. This gives enough flexibility while at the same time keeping the number of configurations and complexity lower.

Figure 31-12 below illustrates integration of the GPO feature.

Figure 31-12. ESC SS General Purpose Output Integration



NOTE: In Figure 31-12 above, the synchronisation between CLK100 or CLK25 with respect to SysClk is not shown and it is implicit by design. Local host shall adjust for the synchronisation delays as required while processing the data in either direction.

31.2.10 Distributed Clocks – Sync & Latch Integration

Distributed clocks (DC) is a differentiating feature of the EtherCAT network. Distributed clocks allows all the nodes in the EtherCAT network to be bound in tight margin of time to synchronize the events and EtherCAT master command.

This feature has sub-features as listed below. To enable the utility of these features at the application level, the related signals of DC are integrated tightly with the C2000 control loop logic, as well as, an external component which could be a possible implementation to trigger/latch other components on the board. This chapter explains the integration of these signals and related nuances of usage.

Distributed clock features:

- Clock Synchronization
- Sync Signal Generation
- Latch Signal event capture

Apart from usage for Control loop synchronizations, these features are also used to synchronize the system and network time. These include the following:

- System Time PDI Controlled : Synchronize System time between two different EtherCAT networks.
- Communication Timing: To synchronize slave communication either with Sync signals, output or input events, etc.

Refer to Beckhoff documentation for further details.

31.2.10.1 Clock Synchronization

DC clock synchronisation is the ability and procedure of the ESC to maintain the copy of reference clock based on local clock (internal 64 bit time base) and other adjustment as derived by the procedure. The reference clock is the most accurate clock in the system and is typically held by one of the slaves (Topologically first one after master is preferred). This time-base has higher accuracy requirement and it needs to periodically synchronize with an absolute time source like GPS or any other maintained time-base as in IEEE1588 network.

The master maintains its own Master clock which is either the absolute time synchronized or it controls the reference clock itself. The master queries the Slave time-base based on topology information and timestamps to determine the drift of the local clock for each ESC with regards to the reference clock and programs the adjustment in each respective ESC. With further periodic queries of the local clock, the master determines the drift of the local clock and keeps adjusting it so as to maintain the copies of the reference clocks on each ESCs in a tight limit. Refer to Beckhoff documentation for more information.

The integration requirement for the clock synchronization is supporting the accurate clock source for the ESC IP. While the IP requires two clocks of 25MHz and 100MHz, the 100MHz clock is used for the internal time-base and supports the best accuracy possible. While the 25ppm requirement is specified for the ESC clock sources, this is too stringent of a need for supporting crystal oscillator and PLL without jitter. A less accurate clock than 25ppm limits the ability of the ESC to act as reference clock. For practical reasons, clock accuracy must be same or better than the Ethernet clock source which is 50ppm.

31.2.10.2 SYNC Signals

Sync signals are the transition created on a pair of signals based on a configured time-base value (reference clock copy), so that these transitions can be used either internal to the ESC or externally to trigger events of interest. SYNC0 is the primary trigger and can be generated in either a cyclic (periodic event generation like rise edge at every x period) or one shot mode. Furthermore, these modes can be either with or without acknowledge, such that when enabled with acknowledge mode, the next event won't be generated until the acknowledgment is received from the controlling master. If the acknowledgment is delayed, the event will be skipped and the next periodic event is generated. Remember that the acknowledgment could be part of the interrupt servicing from the PDI and thus such a delay in triggering the next event is acceptable since the servicing routine can accordingly take action for the period elapsed.

The SYNC1 generation follows the SYNC0 generation with a programmable delay and depending upon the delay time defined, it may or may not generate the pulse since the predefined delay from SYNC0 event is newly measured only after the SYNC1 event (except for the start). The SYNC0/1 when used in a system clock domain is stretched to at least 3 clock wide pulse.

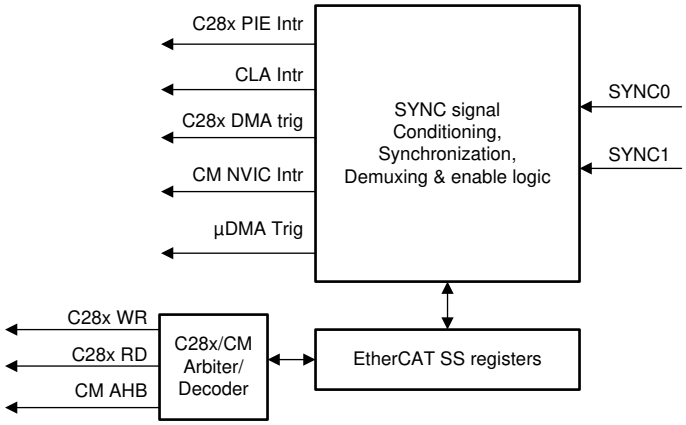
The SYNC control can be used for triggering several system level events of importance in a real-time control loop or real-time communication. Some of the usage points of the same are described below.

31.2.10.2.1 Seeking Host Intervention

SYNC can be used to initiate the action from the local host or related DMA engine which can respond with control action or data transfers from the ESC IP. These actions can be selectively initiated in terms of interrupts to CPU cores (CPU1, CLA or CM) or DMA requests to DMA cores (CPU1 DMA and uDMA).

Figure 31-13 below depicts the SYNC connection diagram to the CPU subsystems.

Figure 31-13. SYNC Integration for the HOST Intervention



The Table 31-9 below shows the Host Intervention selections, control and information that helps applications to route and handle the SYNC signals for respective Host intervention.

Table 31-9. ESC SYNC Integration Map

Destination	Source	Enable	Mask	Clear	Source Clock	Destination Clock	Destination Signaling
C28x PIE Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[0]	ESCSS_INTR_MASK[0]	ESCSS_INTR_CLR[0]	ECAT.100MHz	C28x.SysClk	Pulse
C28x PIE Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[0]	ESCSS_INTR_MASK[1]	ESCSS_INTR_CLR[1]	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C28x DMA Trigger	SYNC0	ESCSS_SYNC0_CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C28x DMA Trigger	SYNC1	ESCSS_SYNC1_CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
CM NVIC Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[3]	ESCSS_INTR_MASK[0]	ESCSS_INTR_CLR[0]	ECAT.100MHz	CM.SysClk	Pulse/Level
CM NVIC Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[3]	ESCSS_INTR_MASK[1]	ESCSS_INTR_CLR[1]	ECAT.100MHz	CM.SysClk	Pulse/Level
uDMA Trigger	SYNC0	ESCSS_SYNC0_CONFIG[4]	NA	NA	ECAT.100MHz	CM.SysClk	Pulse/Level
uDMA Trigger	SYNC1	ESCSS_SYNC1_CONFIG[4]	NA	NA	ECAT.100MHz	CM.SysClk	Pulse/Level

On this MCU, the CLA does not have access to EtherCAT hence it does not have the MASK/Clear controls, however, the trigger would start the action on the CLA processing which upon completion should be acknowledged by CPU1 to clear the cause.

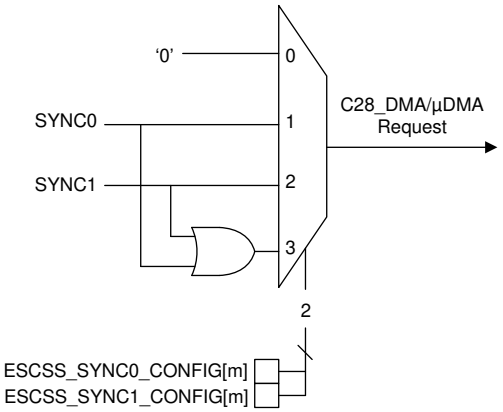
The DMA triggers do not have Mask and Clear capabilities as typically there is no feedback mechanism from the DMA to clear the trigger cause. It is expected that DMA Done is routed to ESCSS and it raises an interrupt to CPU for acknowledgment. CPU1 upon clearing the trigger cause, acknowledges the SYNC through PDI.

The difference between Enable and Mask is that Enable allows the conditioned and synchronized interrupt to be routed to the raw interrupt/trigger cause register, while Mask is a software control to allow raising an interrupt or not. For the DMA, there is no Mask control as there is no Clear mechanism associated, but Enable can be programmed by the master for the same. Disabling the SYNC0/1 on a respective trigger would loose any events that happen until it is enabled again.

31.2.10.2.1.1 Sync Configuration

SYNC0, SYNC1 are precise time controlled signals and are able to trigger time synchronized action(s) of the device master(s). CPU core and DMA engine triggers are configured independently for every end point, Figure 31-14 below is the symbolic view of DMA request source select.

Figure 31-14. SYNC Event Muxing for Different Host DMA Triggers



If a given source event triggers multiple events across different masters then the software has to ensure there is a status exchange before cause is cleared. There is no replication of RIS/ MASK/ MIS/ CLEAR for each master. DMA requests do not have the mask/clear and it is assumed to be handled by edge/pulse behavior of SYNC0/SYNC1 without RIS/ MASK/ MIS/ CLEAR registers.

31.2.10.2.2 Automating Control Triggers and Synchronization of PWMs

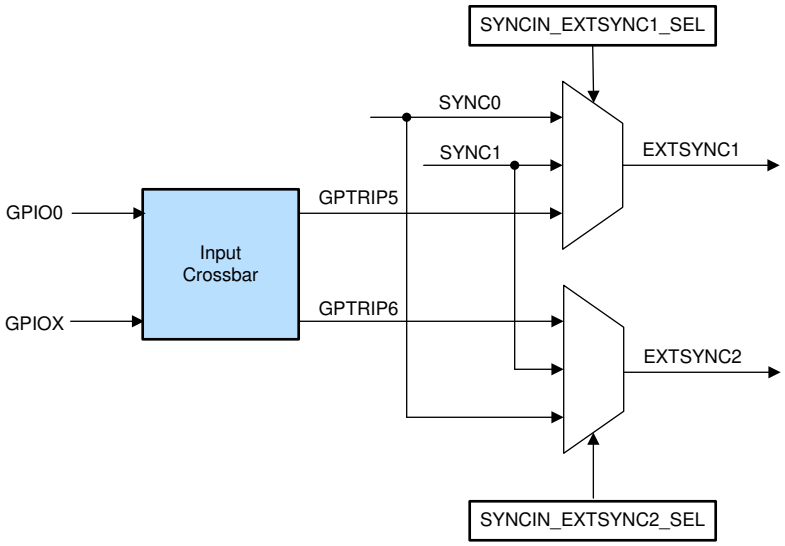
The true benefit and differentiation advantage of the DC functions is when those are tightly integrated with the control functions of the device. The precisely timed pulse/edge nature of the SYNC allows ESC to synchronize the internal resources like PWMs, ECAPs (for capture as well as PWM) with remote system components. The following are the connections which are available for applications to program for allowing this synchronization.

31.2.10.2.2.1 Synchronization of PWM

The PWM Sync-chain on the MCU can be triggered either by the device external inputs from the GPIO via input cross-bar or the PWM internal events when the chain is programmed appropriately. The SYNC0/1 inputs in this implementation also act as the external sync inputs to the PWM sync-chain. The integration as depicted in Figure 31-15 is done to avoid affecting legacy sync-select software and to keep it such that it can be incrementally integrated with the existing schemes.

The additional select register added to the trigger crossbar register allows independent programming of the EXTSYNCx from either GPTRIP or SYNC0/1.

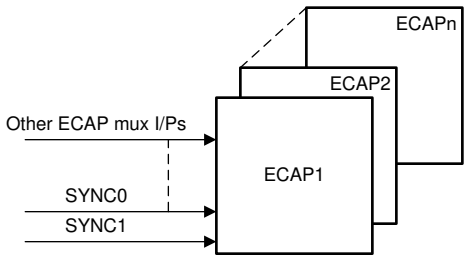
Figure 31-15. SYNC Integration for Control Functions - PWM SYNC



31.2.10.2.2.2 ECAP Input Mux

ECAP supports accurate time capture of events which can be relatively checked against the series of events in vicinity and used for the control loop action. Additionally, ECAP has inbuilt capability of limited PWM action which can be triggered based on the selected input. Hence the SYNC0/1 are also connected to ECAP input mux. The exact select value/vector for SYNC0/1 is defined in the ECAP chapter.

Figure 31-16. SYNC Integration for Control Functions – ECAP

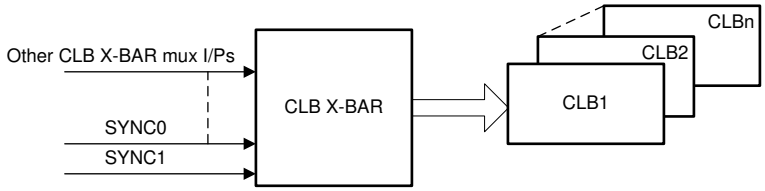


31.2.10.2.3 Conditioning of signal and rerouting to other destinations

SYNC0/SYNC1 when programmed for the respective pulse widths, with or without acknowledgment enabled, can generate various waveform patterns to create different trigger conditions. Additional flexibility to process these signals using the CLB, which can make conditional and/or delay based waveforms, is possible since SYNC0/1 are routed to CLB input mux.

This integration also allows routing SYNC0/1 signals with or without processing to other destinations within the device which are not explicitly connected. Details of the CLB input mux selects are explained in the CLB chapter.

Figure 31-17. SYNC Integration for Signal Conditioning – CLB



31.2.10.2.4 Safe Values for SYNC Outputs until EEPROM Loaded

SYNC outputs can trigger events externally to the device, or within, when the ESC goes through a reset so the output needs to be kept at safe value. At reset this value is '0' and this could be an active state when the reset occurs therefore the corresponding care of usage from the remote device has to be taken. Applications should ensure that the ESC IP outputs driving IOs (at device boundary) are in safe state until EEPROM_LOADED is asserted. The recommendation for the application is to configure SYNC/LATCH only after EEPROM is loaded.

31.2.10.3 LATCH Signals

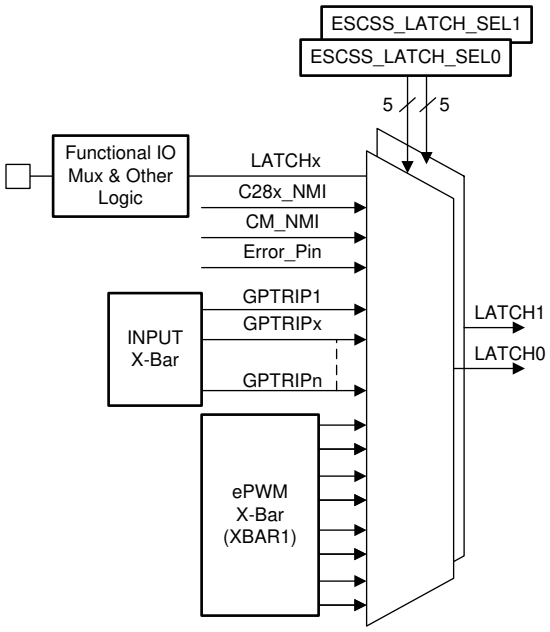
Latch inputs to the ESC IP core can be used to capture the time-stamp or register the GPI inputs. This allows external events:

1. To take the system time snapshot of the EtherCAT network, measure time, or schedule further operations
2. To capture the status of the GPI inputs either as the status of connected external components or as part of control flow. Either of the latch events can be used for this.

Both the Latch inputs can be independently configured to operate on either rising or falling edge of the signal. Additionally it supports the one shot or continuous mode. In one shot mode, the next capture of the timestamp is done on qualifying LATCH event only after the previous one is acknowledged. Where as in continuous mode, time-stamps are successively captured on a qualifying event, regardless of a preceding one being read or not. The LATCH events can be individually assigned either for the PDI control or EtherCAT master control.

Figure 31-18 below depicts the different sources for the LATCH0/1 so as to full-fill the application requirements. These are subsequently explained thereafter for possible use.

Figure 31-18. ESC Latch Input Integration



The details of connections and mux select to these muxes is shown in Table 31-10 and selection is possible individually for each of the LATCH0 or LATCH1 signal.

Table 31-10. ESC LATCH0/1 Trigger Table

31.2.10.3.1 Timestamping the Device Internal Events Coming from Control Logic

Timestamping allows the remote EtherCAT master to measure the time events and plan the subsequent controls. The EPWM cross-bar has all the critical signals aggregated which allows for a variety of options for input triggers. The same outputs of the EPWM crossbar that connect to the 8 EPWMs can be used as 8 input signals (PWMXBAROUT0-PWMXBAROUT7) for time stamping. Effectively the same selections as setup by the user to trip the EPWM are thus used to timestamp the critical trip events in the system.

Note that there is no independent option for Latch muxing as far as EPWM cross-bar inputs are concerned; unless one of the TRIP outputs are not used in control loop and such a crossbar output is dedicated for LATCH0/1 toggle.

31.2.10.3.2 Timestamping the Events External to the Device

This feature of the ESCSS allows other board components apart from the MCU to trigger the timestamp capture. Such a functionality is common for discrete ESC uses hence it is provided in this device. For example, this could be a periodic or in response pulse/edge from an sensor when the sensor data is read or accessed.

Connecting the LATCH0/1 controls through the input crossbar allows timestamp capture based on any selected GPIO toggle (such as GPTRIP15 or GPTRIP16). Two GPTRIPs are provided for independent GPIO choice for LATCH0 and LATCH1. GPTRIP1,2,3 allow the same functionality however those could be utilized for EPWM trip zone functions where pins may or may not need to match. In the case a trip zone based on GPTRIP is to be latched, one of these inputs can be used.

An independent GPIO input buffer connection is provided in this mux which is the default connection of mux selection. The mux selection could be based on user choice to allow LATCH0/1 function or not.

31.2.10.3.3 Timestamping the Device Exception Events for Debug and Data-logging

Besides external and control inputs, LATCH based timestamping can also help logging the exception events within the device. This can be used by both local application through PDI and remote master to diagnose or debug the system. It can also be used to collect periodic information to find out systemic issues in the system. NMI from both the cores are connected to the mux for this reason. Also, particular accesses or data patterns/counts on the CPU bus can be tracked through compare triggers from ERAD. Please refer to ERAD chapter for further details on this.

31.3 Interfacing to Device

This section details the various options available to interface the ESC with the other peripherals of the device.

31.3.1 Interface to CPU1 CLA1

On this MCU, CLA1 does not have access to read/write to the etherCAT registers and RAM but the following can trigger a CLA task.

1. ECATSYNC0 pulse
2. ECATSYNC1 pulse

31.3.2 Interface to DMA

On this MCU, both CM DMA (uDMA) and CPU1 DMA have access to the ESC register space depending on the ownership of the ESC peripheral and this is shown in address map in section Section 31.2.1.2 and Section 31.2.1.1, respectively for CM and C28.

In addition to the ESC register address space, ESC SYNC0/SYNC1 is one of the triggers to the CPU1 DMA engine and is not gated by the ESC allocation (PALLOCATE) of the ESC peripheral.

On CM, the ESC SYNC0/SYNC1 can be selected as one of the trigger sources for a Burst transfer (further explained in the uDMA Channel mapping in the uDMA chapter). This is not gated by the ESC allocation (PALLOCATE) of the ESC peripheral.

Refer to Section 31.2.10.2.1.1 for uDMA and DMA connections and also refer to section Section 31.2.5.1 for more details.

31.3.3 Interface to CLB

On this MCU, SYNC0 and SYNC1 are routed to CLB for further signal conditioning as shown in Section 31.2.10.2.3 and for further details, refer to the CLB chapter.

These aren't gated by the ESC allocation (PALLOCATE) of the ESC peripheral.

31.3.4 Interface to Peripherals

On this MCU, ESC signals are integrated to NVIC, NMI and DMA on CM as explained in Section 31.2.10.2.1.1 and Section 31.2.5.1. None of these are gated by the ESC allocation (PALLOCATE) of the ESC peripheral.

On CPU1, the ESC signals, are integrated to the following peripherals – EPWM, ECAP, CLB, PIE, NMI, GPIO, XBARs and ERAD as explained in Section 31.2.10.2 and Section 31.2.10.3.

31.4 Software Initialization Sequence and Allocating Ownership

This section details the software initialization sequence when configuring CPU1 or CM as ESC owner. The CM sequence includes details on allocating ownership of the EtherCAT peripheral.

Table 31-11. CPU1 Software Initialization Sequence

Step	Action
1	General device initialization (Configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	Configure Aux Clock for EtherCAT (if using Aux clock as source)
3	Configure GPIOs for EtherCAT (set Pin Configurations, set GPIO qualification mode, set Pad Configuration)
4	Initialize interrupts and register ISR handlers
5	Set EtherCAT clock source and divider. Then configure whether or not EtherCAT PHY will be clocked from device or external PHY clock.
6	Configure the EEPROM size
7	Bring EtherCAT peripheral out of reset via system control register
8	Perform EtherCAT memory initialization and wait until memory initialization is complete
9	(Optional) Enable debug access to the EtherCAT registers
10	(Optional) Check that EEPROM loaded successfully
11	EtherCAT subsystem configurations for interrupt masking, SYNCx connections, etc

Table 31-12. CM Software Initialization Sequence

Step	Core	Action
1	CPU1	General device initialization (Configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	CPU1	Configure GPIOs for EtherCAT (set Pin Configurations, set GPIO qualification mode, set Pad Configuration)
3	CPU1	Allocate EtherCAT peripheral to CM
4	CPU1	Configure CM clocks and release CM from reset to wait mode
5	CPU1	Configure Aux Clock for EtherCAT (if using Aux clock as source)
6	CPU1	Set EtherCAT clock source and divider. Then configure whether or not EtherCAT PHY will be clocked from device or external PHY clock.
7	CPU1	Set CM boot mode and boot CM to start application
8	CPU1	General Device Initialization
9	CM	Initialize interrupts and register ISR handlers
10	CM	Configure EtherCAT EEPROM size
11	CM	Bring EtherCAT peripheral out of reset via system control register
12	CM	Perform EtherCAT memory initialization and wait until memory initialization is complete
13	CM	(Optional) Enable debug access to the EtherCAT registers
14	CM	(Optional) Check that EEPROM loaded successfully
15	CM	EtherCAT subsystem configurations for interrupt masking, SYNCx connections, etc

31.5 ESC Configuration Constants

Table 31-13. ESC Configuration Constants Table

Name	Value
ESC Type	0x91
Revision	0x0
Build	0x0
FMMU Supported	0x8
SyncManagers	0x8
RAM Size	0x10
Port Descriptor	0xF
ESC Features Supported	0x1CC
Product ID	0x0
Vendor ID	0x0

31.6 EtherCAT Registers

This section describes the EtherCAT Slave Controller Registers.

31.6.1 EtherCAT Base Addresses

Table 31-14. ECAT Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
EcatssRegs	ECATSS_REGS	ESC_SS_BASE	0x0005_7E00	YES	-	-	-	YES
EcatssConfigRegs	ECATSS_CONFIG_REGS	ESC_SS_CONFIG_BASE	0x0005_7F00	YES	-	-	-	YES

Table 31-15. CM ECAT Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
ESC_SS_BASE	0x400A_FC00	-	-
ESC_SS_CONFIG_BASE	0x400A_FE00	-	-

31.6.2 ESCSS_CONFIG_REGS Registers

Table 31-16 lists the ESCSS_CONFIG_REGS registers. All register offset addresses not listed in Table 31-16 should be considered as reserved locations and the register contents should not be modified.

Table 31-16. ESCSS_CONFIG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	ESCSS_CONFIG_LOCK	EtherCATSS Configuration Lock		Go
2h	ESCSS_MISC_IO_CONFIG	RESET_IN, EEPROM IO connections select	LOCK	Go
4h	ESCSS_PHY_IO_CONFIG	Control Register of ESCSS		Go
6h	ESCSS_SYNC_IO_CONFIG	SYNC Signals IO configurations	LOCK	Go
8h	ESCSS_LATCH_IO_CONFIG	LATCH inputs IO pad select	LOCK	Go
Ah	ESCSS_GPIN_SEL	GPIN Select between IO PAD & tieoff	LOCK	Go
Ch	ESCSS_GPIN_IOPAD_SEL	GPIN IO pad Select	LOCK	Go
Eh	ESCSS_GPOUT_SEL	GPOUT IO pad connect select	LOCK	Go
10h	ESCSS_GPOUT_IOPAD_SEL	GPOUT IO pad select	LOCK	Go
12h	ESCSS_LED_CONFIG	Selection of LED o/p connect to IO pad	LOCK	Go
14h	ESCSS_MISC_CONFIG	Miscelleneous Configuration	LOCK	Go

Complex bit access types are encoded to fit into small table cells. Table 31-17 shows the codes that are used for access types in this section.

Table 31-17. ESCSS_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

31.6.2.1 ESCSS_CONFIG_LOCK Register (Offset = 0h) [reset = 0h]

ESCSS_CONFIG_LOCK is shown in Figure 31-19 and described in Table 31-18.

Return to the Summary Table.

Lock bit for EtherCAT configuration registers

31-16	RESERVED	R-0	0h	Reserved
15-8	WRITE_KEY	R-0/W	0h	The key value should be 0xa5 for the writes to bit 0 take effect. Writes of other values will be ignored. Reset type: ECAT.XRSn
7-5	RESERVED	R-0	0h	Reserved
4	IO_CONFIG_ENABLE	R/W	0h	This bit enables the IO configurations allowing the EtherCAT ports to take effect. Till this bit is written EtherCAT ports are not connected to the IO pad. Enable takes effect when this bit is set to 1. Changing IO selections or IO configurations after this bit is set can have unpredictable IO behavior on the device IOs. Reset type: ECAT.XRSn
3-1	RESERVED	R-0	0h	Reserved
0	LOCK_ENABLE	R/WSonce	0h	This bit enables locking the contents of all the EtherCAT configuration registers. The lock takes effect when this bit is set to 1. This bit can be set only once after ecatXRSN and gets reset after the next ecatXRSN. Reset type: ECAT.XRSn

31.6.2.2 ESCSS_MISC_IO_CONFIG Register (Offset = 2h) [reset = 2h]

ESCSS_MISC_IO_CONFIG is shown in Figure 31-20 and described in Table 31-19.

Return to the Summary Table.

20h	ESCSS_SYNC0_CONFIG	SYNC0 Configuration for various triggers	LOCK	Go
22h	ESCSS_SYNC1_CONFIG	SYNC1 Configuration for various triggers	LOCK	Go

Complex bit access types are encoded to fit into small table cells. Table 31-30 shows the codes that are used for access types in this section.

Table 31-30. ESCSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 31-30. ESCSS_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

31.6.3.1 ESCSS_IPREVNUM Register (Offset = 0h) [reset = 0h]

ESCSS_IPREVNUM is shown in Figure 31-30 and described in Table 31-31.

Return to the Summary Table.

IP Revision number showing the Major & Minor IP versions 4 bit each

Figure 31-30. ESCSS_IPREVNUM Register

Table 31-32. ESCSS_INTR_RIS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	MASTER_RESET_RIS	R	0h	Indicates Raw Status of the EtherCAT Master Reset event , until cleared by ESCSS_INTR_CLR 0: EtherCAT Master Reset Event did not happen since last IP reset or last clear of this bit and ECAT Master reset programmed to be Interrupt to local host. 1: EtherCAT Master Reset Event has occured. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Information of this event is lost if ECAT Master event is programmed to be reset IP. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_RIS	R	0h	Indicates Raw Status of the past event on PDI access timeout Error, until cleared by ESCSS_INTR_CLR 0: PDI Access Timeout Error Event did not happen since reset or last clear of this bit. 1: PDI Access Timeout Error Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask as long as Timeout is enabled, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn

Table 31-32. ESCSS_INTR_RIS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	DMA_DONE_RIS	R	0h	Indicates Raw Status of the past event on DMA Done, until cleared by ESCSS_INTR_CLR 0: DMA Done Event did not happen since reset or last clear of this bit. 1: DMA Done Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
2	IRQ_RIS	R	0h	Indicates Raw Status of the past event on EtherCATSS IRQ, until cleared by ESCSS_INTR_CLR 0: EtherCATSS IRQ Event did not happen since reset or last clear of this bit. 1: EtherCATSS IRQ Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
1	SYNC1_RIS	R	0h	Indicates Raw Status of the past event on SYNC1, until cleared by ESCSS_INTR_CLR 0: SYNC1 Event did not happen since reset or last clear of this bit. 1: SYNC1 Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
0	SYNC0_RIS	R	0h	Indicates Raw Status of the past event on SYNC0, until cleared by ESCSS_INTR_CLR 0: SYNC0 Event did not happen since reset or last clear of this bit. 1: SYNC0 Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn

31.6.3.3 ESCSS_INTR_MASK Register (Offset = 4h) [reset = 0h]

ESCSS_INTR_MASK is shown in Figure 31-32 and described in Table 31-33.

Return to the Summary Table.

Allows to mask individual interrupt cause impacting the interrupt

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	MASTER_RESET_MASK	R/W	0h	Masks EtherCAT Master reset event against any effect on interrupts or other CPU Interrupts. 1: EtherCAT Master Reset affects the interrupt/DMA trigger. 0: EtherCAT Master Reset masked and does not affect Interrupt. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_MASK	R/W	0h	Masks PDI access timeout Error to have effect on interrupts or other CPU Interrupts. 1: PDI Access Timeout Errors affects the interrupt/DMA trigger. 0: PDI Access Timeout Errors masked and does not affect Interrupt. Reset type: ECAT.IPRSn
3	DMA_DONE_MASK	R/W	0h	Masks DMA Done status update to have effect on interrupts or other CPU Interrupts. 1: DMA Done affects the interrupt/DMA trigger. 0: DMA Done masked and does not affect Interrupt. Raw DMA Done status is updated regardless of this setting. Reset type: ECAT.IPRSn
2	IRQ_MASK	R/W	0h	Masks EtherCATSS IRQ to have effect on interrupts or other CPU/DMA triggers. 1: EtherCATSS IRQ affects the interrupt/DMA trigger. 0: EtherCATSS IRQ masked and does not affect Interrupt/DMA trigger. Raw EtherCATSS IRQ status is updated regardless of this setting. Reset type: ECAT.IPRSn
1	SYNC1_MASK	R/W	0h	Masks SYNC1 to have effect on interrupts or other CPU/DMA triggers as programmed in HOST_TRIG_MAP registers. 1: SYNC1 affects the interrupt/DMA trigger. 0: SYNC1 masked and does not affect Interrupt/DMA trigger. Raw SYNC1 status is updated regardless of this setting. Reset type: ECAT.IPRSn
0	SYNC0_MASK	R/W	0h	Masks SYNC0 to have effect on interrupts or other CPU/DMA triggers as programmed in HOST_TRIG_MAP registers. 1: SYNC0 affects the interrupt/DMA trigger. 0: SYNC0 masked and does not affect Interrupt/DMA trigger. Raw SYNC0 status is updated regardless of this setting. Reset type: ECAT.IPRSn

31.6.3.4 ESCSS_INTR_MIS Register (Offset = 6h) [reset = 0h]

ESCSS_INTR_MIS is shown in Figure 31-33 and described in Table 31-34.

Return to the Summary Table.

Registers the Msked Interrupt status of different interrupt triggers. This is AND of RIS & MASK of respective fields

Fast Serial Interface (FSI)

This chapter contains a general description of the Fast Serial Interface (FSI) module. The FSI is a serial peripheral capable of reliable high-speed communication across isolation barriers.

Topic **Page**

32.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, they can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to ensure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, please refer to the following source:

- http://www.ti.com/lit/an/spracj9/spracj9.pdf

32.2 Features

The FSI module includes the following features:

- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- DMA support
- CLA task triggering
- SPI compatibility mode (limited features available)
- Tag match notifications
- Multi-slave support

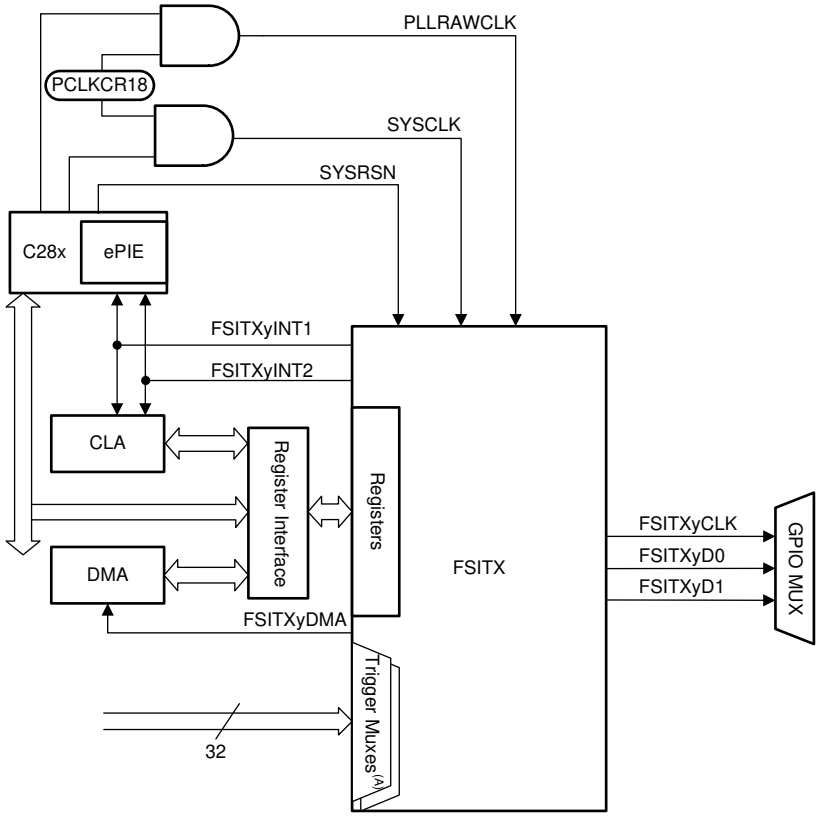
32.3 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features may require additional configuration of modules that are not within the scope of this chapter, the details of which can be found elsewhere in this document.

32.3.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.

Figure 32-1. FSI Transmitter (FSITX) CPU Interface



A The signals connected to the trigger muxes are described in Section 32.3.6.

Figure 32-2. FSI Receiver (FSIRX) CPU Interface

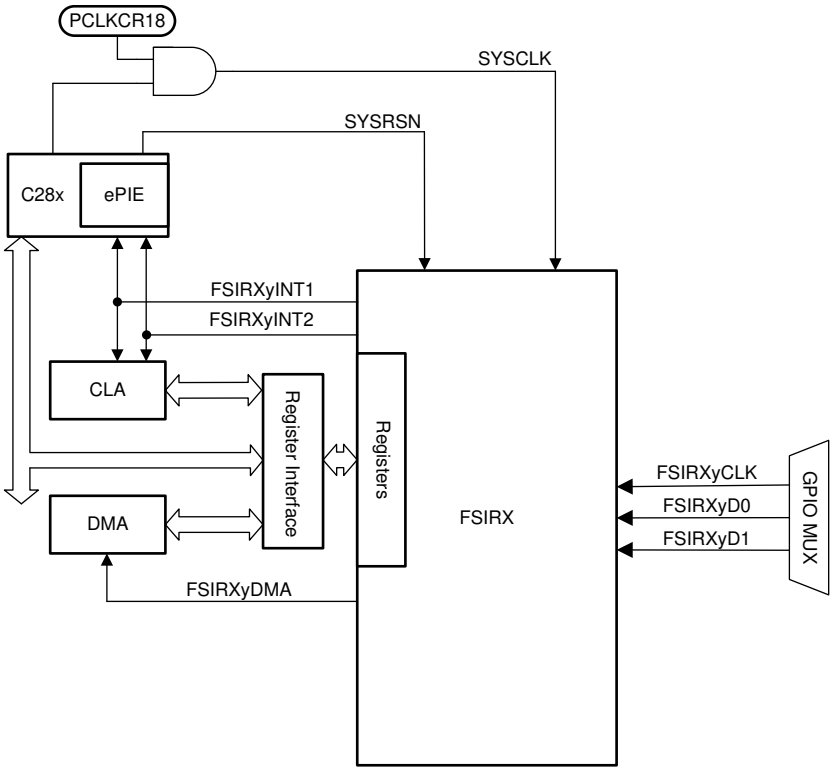


Figure 32-3. FSI Receiver (FSIRX) CPU Interface with CLB

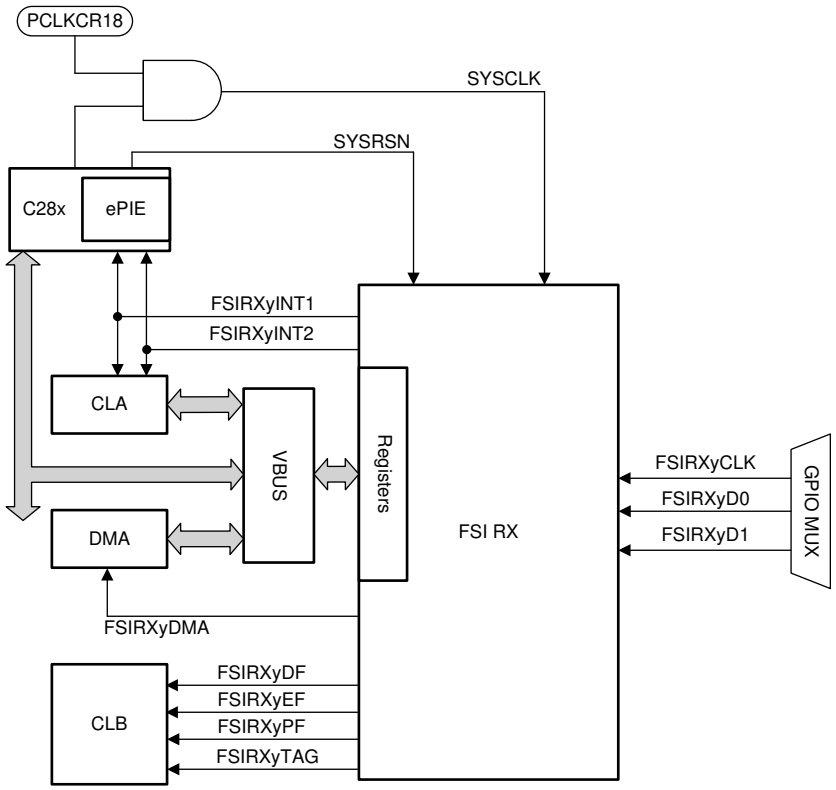

32.3.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core will communicate directly to a single FSI receiver core. Similarly, an FSI receiver core will receive data from a single FSI transmitter core.

Each FSI core has three signals associated with it: one clock and two data signals. Data is always transmitted or received with the most significant bit of each frame field being first. If multi-lane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and their GPIOs repurposed for other application needs. Table 32-1 and Table 32-2 describe the various signals that can be selected by the GPIO mux to be brought out to device pins.

Table 32-1. FSI Transmitter Core Signals

Signal Name	Direction	Description	Inactive Level[1]
TXCLK	Output	This is the transmit clock. It is driven by the FSI transmit module. During a transmission, four clock edges will be transmitted before the start of frame phase (premable) and four clock edges will follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock. In SPI compatibility mode, the preamble and the post frame clock edges will not be transmitted. Data is transmitted only on one edge of the clock. Data will transmit on rising edge and received on falling edge of the clock.	Logic High
TXD0	Output	This is the primary data output line for transmission. This signal is driven by the FSI transmit module. When the FSI is configured for multi-lane transmission, TXD0 will contain all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame will be transmitted in full.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

Table 32-1. FSI Transmitter Core Signals (continued)

Signal Name	Direction	Description	Inactive Level[1]
TXD1	Output	This is an additional data output line for transmission if the FSI is configured for multi-lane transmission. This signal is driven by the FSI transmit module. During transmission, the data bits are split between TXD0 and TXD1. TXD1 will contain all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line will be identical to TXD0.	Logic High

Table 32-2. FSI Receiver Core Signals

Signal Name	Direction	Description	Inactive Level[1]
RXCLK	Input	This is the receive clock input signal for the FSI receive module. This must should be connected to TXCLK of the transmitting FSI module.	Logic High
RXD0	Input	This is the primary data input line for reception. This should be connected to the TXD0 of the transmitting FSI module.	Logic High
RXD1	Input	This is an additional data input line for reception. This signal should be connected to the TXD1 of the transmitting FSI module if multi-lane transmission is used.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively receiving data.

32.3.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See *General Purpose Input-Output*, Chapter 15, for more details on the GPIO mux and settings.

32.3.3 Interrupts

Each FSI module contains multiple interrupt sources which can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT_STS, EVT_FRC, and the EVT_CLR registers, respectively.

NOTE: Because the transmitter and receiver cores have their own distinct register sets, the preceding 'TX_' and 'RX_' will be left off of the register names unless otherwise noted.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX_INT_CTRL register. The receiver events are assigned an interrupt vector using RX_INT1_CTRL and RX_INT2_CTRL registers. If an interrupt is not required, ensure the bit is not set in the respective INT_CTRL register.

32.3.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME_DONE)**
  This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF_UNDERRUN)**

This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet be written to by the CLA, CPU, or DMA.

- **Buffer Overrun (BUF_OVERRUN)**
  The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun may occur if a piece of data is overwritten before it has been transmitted.
- **Ping Frame Triggered (PING_TRIGGERED)**
  The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit will be set when the ping counter has timed out or an external ping trigger event has occurred.

32.3.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events. These events are described below.

- **Ping Watchdog Timeout (PING_WD_TO)**
  This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX_PING_WD_REF register.
- **Frame Watchdog Timeout (FRAME_WD_TO)**
  This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX_FRAME_WD_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter will start counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog will time out and this event will be generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **CRC Error (CRC_ERR)**
  This error indicates that a CRC error has occurred. A CRC error will be generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE_ERR)**
  This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **End-of-Frame Error (EOF_ERR)**
  This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization in order to guarantee proper operation.
- **Receive Buffer Overrun (BUF_OVERRUN)**
  This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF_UNDERRUN)**
  This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads the buffer while it is empty.
- **Frame Done (FRAME_DONE)**
  This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR_FRAME)**
  This event indicates that an error frame has been received.
- **Ping Frame Received (PING_FRAME)**
  This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME_OVERRUN)**
  This event indicates that a new frame has been received while the FRAME_DONE flag was still set.
- **Data Frame Received (DATA_FRAME)**
  This event indicates that a data frame has been received.
- **Ping Tag Matched (PING_TAG_MATCH)**
  This event indicates that a ping frame with a matching tag has been received.
- **Data Tag Matched (DATA_TAG_MATCH)**
  This event indicates that a data frame with a matching tag has been received.
- **Error Tag Matched (ERROR_TAG_MATCH)**
  This event indicates that an error frame with a matching tag has been received.

32.3.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application should select the interrupt vector for each desired event using the TX_INT_CTRL register for the transmitter, and RX_INT1_CTRL and RX_INT2_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

NOTE: If an event is registered for both interrupt vectors, both interrupts will fire. There are no hardware checks for overlapping interrupt vector assignments.

32.3.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user should clear the event flag using the EVT_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt will be generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This may cause the application to miss events that may be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine will be similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX_EVT_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events which require action.
- Perform the necessary actions for each fo the events seen in the snapshot.
- Write to the receive event and error clear register (RX_EVT_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag may still be set at the end of the ISR. As soon as the ISR completes, a new interrupt will be generated and this flag will still be set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR may cause race conditions which will cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both are handled within the same interrupt line, the software may only respond to one of the events if they both occur close in time.

32.3.4 CLA Task Triggering

In addition to generating interrupt vectors to the PIE, both interrupts lines for each module TX_INT1, TX_INT2, RX_INT1, and RX_INT2 can be assigned to trigger CLA tasks. Refer to the Configuration options table for the list of all sources capable of CLA task triggering. The configuration and use of CLA tasks are described in the Section 8.3.4. The CLA has access to the entire FSI register map. This allows the CLA to manage the FSI independently from the CPU, freeing it up for other tasks.

32.3.5 DMA Interface

Both the transmitter and receiver are capable of using the DMA for automatic data transfers. The DMA trigger is independent from the interrupt signals. DMA events are only triggered on the completion of a data frame.

The transmitter DMA trigger is enabled by setting TX_DMA_CTRL.DMA_EVT_EN to 1. The transmitter must also set TX_OPER_CTRL_LO.START_MODE to 0x2 to allow either a write to the TX_FRAME_CTRL.START bit or to the TX_FRAME_TAG_UDATA register to start the transmission.

The receiver DMA trigger is enabled by setting RX_DMA_CTRL.DMA_EVT_EN to 1.

Refer to Section 32.4.2 and Section 32.4.3 for more DMA information specific to each FSI Module.

32.3.6 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and/or generic frames. These muxes are independently configured for each type of frame. The application may select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX_PING_CTRL.EXT_TRIG_SEL to the index of the desired trigger. TX_PING_CTRL.EXT_TRIG_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX_OPER_CTRL_HI.EXT_TRIG_SEL to the index of the desired trigger. TX_OPER_CTRL_LO.START_MODE must be set to 0x1 in order for a frame to be transmitted by an external trigger.

32.4 FSI Operation

32.4.1 Introduction to Operation

The transmitter and receiver modules are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

32.4.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU, CLA, and the DMA.

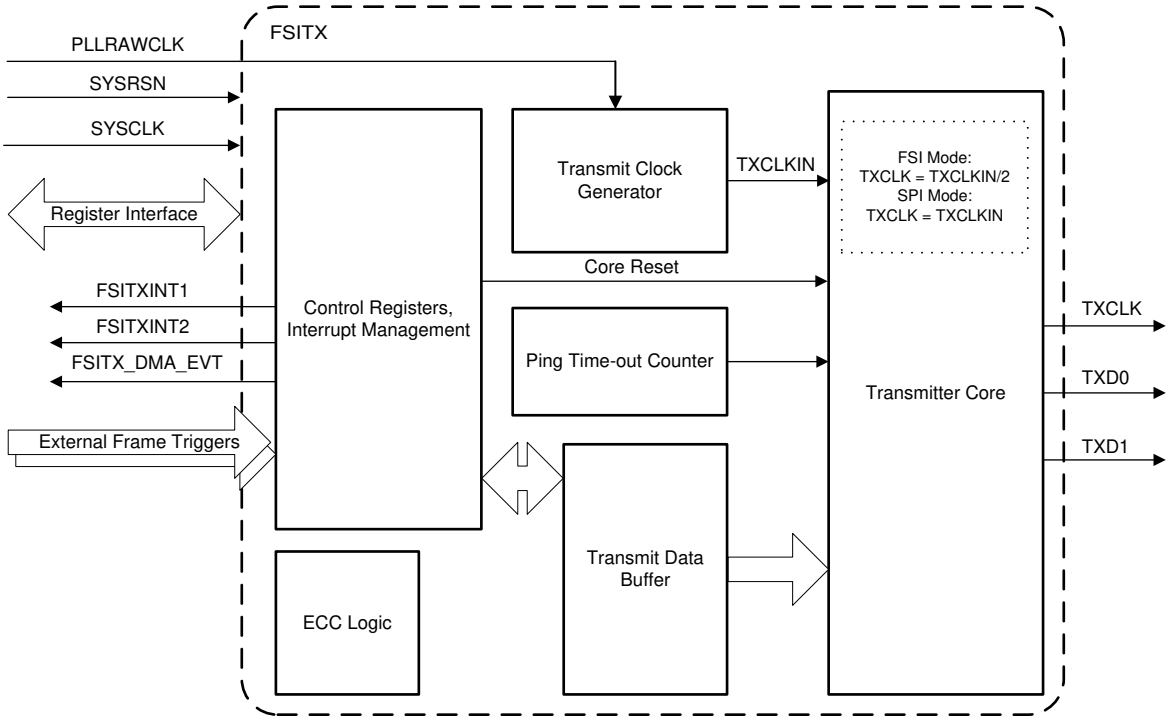
The transmitter has the following features:

- Automated ping frame generation
- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data

- DMA support
- CLA task triggering

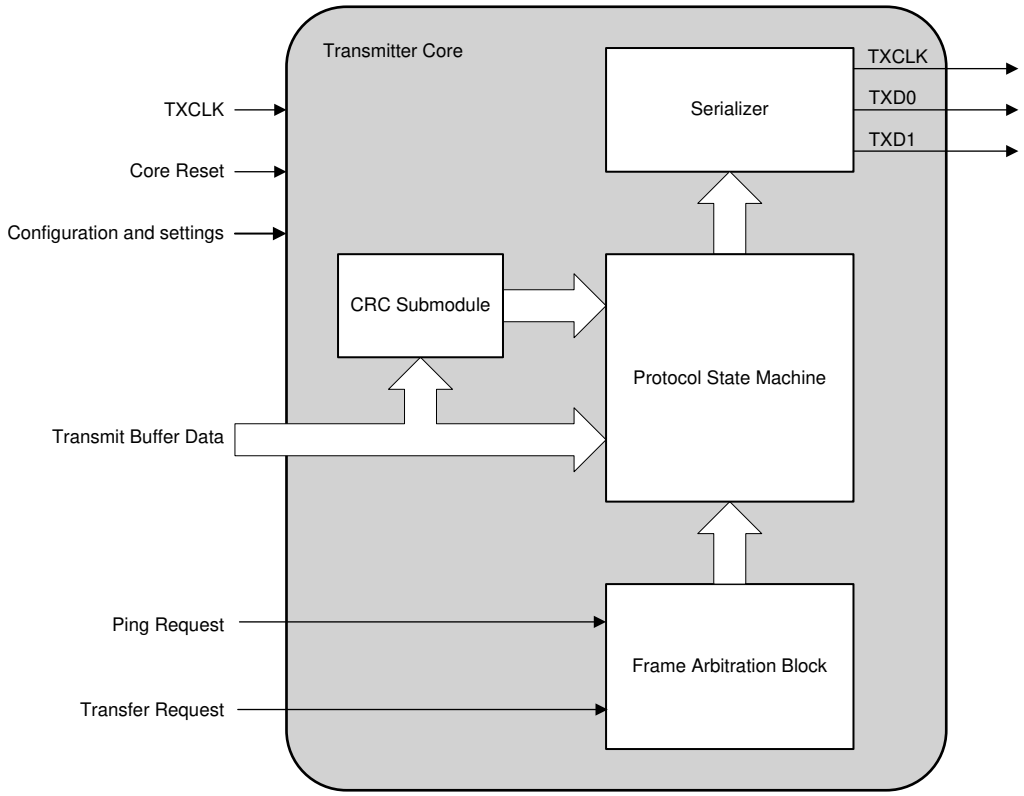
Figure 32-4 shows the high-level block diagram of the FSI transmitter. Figure 32-5 shows the block diagram of the transmitter core submodule.

Figure 32-4. FSI Transmitter Block Diagram



The block diagram of the transmitter core submodule is shown in Figure 32-5.

Figure 32-5. FSI Transmitter Core Block Diagram



The following sections describe the various aspects of the FSI transmitter in detail.

32.4.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module should execute the following initialization sequence in order to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX_CLK_CTRL.CLK_RST to 1 and subsequently clearing it.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX_OPER_CTRL_LO.SEL_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX_CLK_CTRL.PRESCALE_VAL.
4. Enable the transmitter clock divider by setting TX_CLK_CTRL.CLK_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX_MASTER_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX_MASTER_CTRL

After initialization and configuration, the transmitter module should synchronize with receiver module before transmitting. The synchronization sequence is described in Section 32.5.1.

CAUTION

Do not change TX_CLK_CTRL.PRESCALE_VAL while the clock is enabled (TX_CLK_CTRL.CLK_EN = 1). Doing so may cause undefined behavior.

32.4.2.2 Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX_CLK_CTRL.PRESCALE_VAL) then setting the clock divider enable bit (TX_CLK_CTRL.CLK_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX_CLK_CTRL.PRESCALE_VAL = 0x0 or 0x1) through 255(TX_CLK_CTRL.PRESCAL_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

CAUTION

TXCLK should never be configured to be faster than SYSCLK.

32.4.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps may be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
   - Set the user data
   - Write to the data buffer
   - Set the word length if the frame is a software defined frame length
4. Set the start condition

NOTE: Note: There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior will be as follows:

- The transmitted frame structure will be exactly like an NWORD data frame. The size of the data frame will be determined by the value in the TX_FRAME_CTRL.N_WORDS register.
- The frame type field of the transmitted data frame will be transmitted as programmed. If this is received by an FSI receiver, it will generate a Type error.

This mechanism can be used for force a Type error in a received frame for testing purposes.

The following sections describe the specific configuration for each frame type and start condition.

32.4.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps should be executed. Steps 1-6 may be executed in any order before setting TX_FRAME_CTRL.START. Some fields may not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and will be re-transmitted in the subsequent frame unless they are modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX_FRAME_CTRL.FRAME_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX_FRAME_CTRL.N_WORDS to 1 less than the number of words to be transmitted if TX_FRAME_CTRL.FRAME_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words will be transmitted, N = 16, set TX_FRAME_CTRL.N_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware will calculate the CRC to be transmitted. If TX_OPER_CTRL_LO.SW_CRC is 1, the application may calculate a custom CRC value and then set TX_USER_CRC to the result.

5. Set TX_FRAME_TAG_UDATA.FRAME_TAG to the desired tag.
6. Set TX_FRAME_TAG_UDATA.USER_DATA to the desired user data.
7. Set TX_FRAME_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX_FRAME_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX_EVT_STS.FRAME_DONE.

32.4.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See Section 32.3.6 for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in Section 32.4.2.3.1. The only difference is that in Step 7, the start condition will be automatically set when the external trigger condition is met rather than by software.

It is important to note that by externally triggering frames, the frame information to be sent will be pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX will take the data as is, and the application software should ensure that this data has been updated as necessary.

Using TX_EVT_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

32.4.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

32.4.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX_PING_CTRL.CNT_RST.
2. Set the desired ping tag to TX_PING_TAG.TAG.
3. Set the ping timer reference value to TX_PING_TO_REF.TO_REF.
4. Enable the ping timer by writing 1 to TX_PING_CTRL.TIMER_EN.

The ping timer is a free-running counter which will count up from 0. The current value of the ping timer counter is found in TX_PING_TO_CNT. When the current value of TX_PING_TO_CNT matches the reference value TX_PING_TO_REF.TO_REF, TX_EVT_STS.PING_TRIGGERED will be set. TX_PING_TO_CNT will reset to 0 and resume counting until the next match has occurred or the ping timer is halted by software (TX_PING_CTRL.TIMER_EN is set to 0).

32.4.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX_FRAME_CTRL.FRAME_TYPE to 0000’b to denote that the frame being sent will be a Ping Frame.
2. Set TX_FRAME_TAG_UDATA.FRAME_TAG to the desired value.
3. Write 1 to TX_FRAME_CTRL.START. This will start the transmission.

Once the frame transmission has started, the TX_FRAME_CTRL.START will be cleared by hardware. To monitor if the frame has completed, the software can poll TX_EVT_STS.FRAME_DONE.

32.4.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers may be selected. See Section 32.3.6 for the list of input sources.

CAUTION

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX_PING_CTRL.EXT_TRIG_EN is set to 1, it will take precedence and the ping timer will be ignored.

32.4.2.3.4 Transmitting Frames with DMA

The FSI transmitter can send data which is continuously fed with the DMA. A DMA trigger will be generated every time a data frame transmission is completed. This is concurrent with the FRAME_DONE signal that sets the TX_EVT_STS.FRAME_DONE flag.

In order to transmit continuous data with the DMA, some configurations need to be made on the transmitter:

First, set TX_DMA_CTRL.DMA_EVT_EN to 1. This will allow the DMA trigger to propagate to the DMA module. Next, TX_OPER_CTRL_LO.START_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX_FRAME_CTRL.START or TX_FRAME_TAG_UDATA..

The DMA must also be configured properly for the FSI to send the data. One possible solution of using the DMA to continuously feed the transmit buffer is shown below:

- Set up two DMA channels to be triggered by the same FSI transmitter and DMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps the after 16 words are copied.

NOTE: Because the frame tag and user data must written in to in order to initiate the transmission of the frame, use two consecutive DMA channels. This ensures that the DMA channels are always executed in sequence. The DMA channel servicing the data buffer should be the lower numbered channel and the tag/user data channel should be the next. For example, configure DMA channel 3 to service the data buffer, and configure DMA channel 4 to service the tag and user data.

32.4.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer from which it pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX_BUF_PTR_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. This mode of operation is the only way in which the overrun, underrun, and pointer status are meaningful. If data is being sourced by the DMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, it means that the buffer went out of sync. This would not only affect the current transfer, but all future transfers also could not be guaranteed due to the ring buffer. Under such conditions, the underrun would need a soft reset to cleanly recover. Alternately, the software could manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and will guarantee a full reset of the control registers.

Due to the flexibility of the transmit buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields may be ignored without adversely affecting the transmitter capability. Additionally, the CURR_WORD_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX_BUF_PTR_LOAD. This will force the transmitter to start picking the data from the indicated location in the buffer.

32.4.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX_OPER_CTRL_LO.SW_CRC appropriately.

If hardware CRC generation is selected (TX_OPER_CTRL_LO.SW_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial 0x7 ($x^8 + x^2 + x + 1$). The transmitter module will automatically compute the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC Submodule, refer to Section 32.4.7.

If software CRC generation is selected (TX_OPER_CTRL_LO.SW_CRC = 1), the CRC must be computed by software and placed in the TX_USER_CRC register. The next frame to be transmitted will use the value placed in the TX_USER_CRC register in place of the CRC value generated by the hardware.

As the TX_USER_CRC register is software-programmable, the application may use this field as an extra data field for application specific purposes. If TX_USER_CRC is used in this manner, the CRC detection on the receiver will not be valid and should be ignored.

32.4.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt may or may not require a soft reset in order to resume proper operation. This determination is up to the application software. Refer to Section 32.4.2.4 for more information on the transmit buffer.

32.4.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX_MASTER_CTRL.CORE_RST.

A module reset will cause the registers to be reset to their default state.

32.4.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after they pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU, CLA, and the DMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- DMA support
- CLA task triggering
- SPI compatibility mode

Figure 32-6 provides a high-level overview of the internal modules present in the FSI receiver. Figure 32-7 shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

Figure 32-6. FSI Receiver Block Diagram

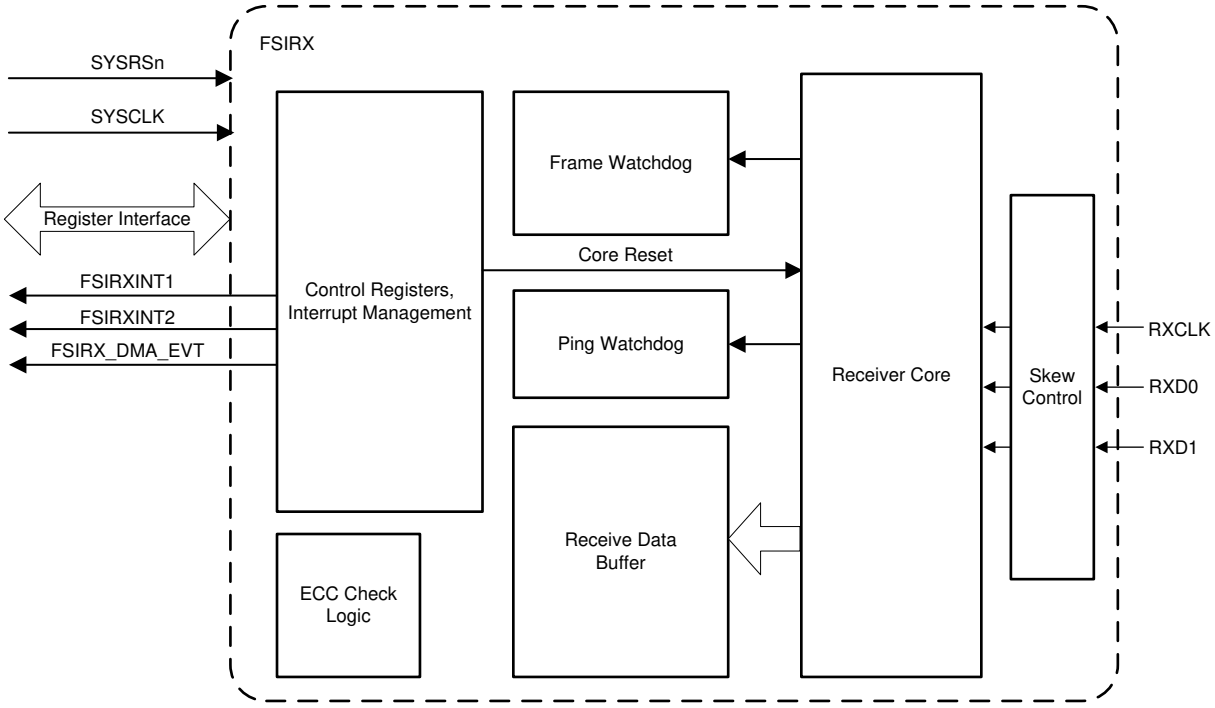


Figure 32-7. FSI Receiver Core Block Diagram

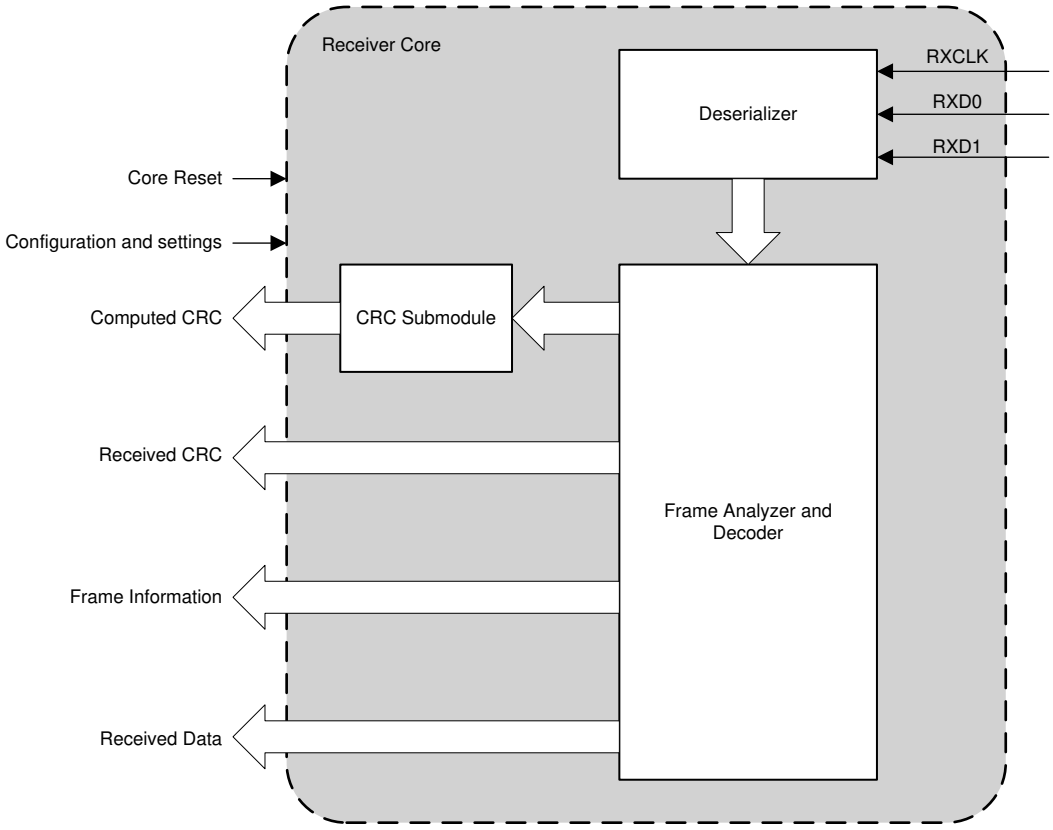


The following sections describe the various aspects of the FSI receiver module

32.4.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module should assert and release the receiver core reset bit (RX_MASTER_CTRL.CORE_RST) prior to any other initialization. Once the receiver module is initialized, the following steps may be executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See Section 32.4.3.4 for configuration details.
3. If required, configure the frame watchdog to ensure that each frame is received within a predetermined window. See Section 32.4.3.5 for configuration details.
4. Initialize the receive buffer pointer by writing to the RX_BUF_PTR_LOAD register. Received data will be placed into the buffer starting with the address loaded in this register.
5. Ensure all errors and flags have been cleared from the RX_EVT_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX_EVT_STS register for various conditions. For example, when the RX_EVT_STS.FRAME_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application should configure the various features such as the ping and frame watchdogs, DMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in Section 32.5.1.

32.4.3.2 Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

CAUTION

RXCLK should never be faster than SYSCLK.

32.4.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. It is important to note that there is no equivalent to a chip select signal to gate incoming data. Every valid clock edge will latch data into the receiver.

The header information of the received frame will be placed in their respective register fields.

- RX_FRAME_INFO.FRAME_TYPE will contain the received frame type.
- RX_FRAME_TAG_UDATA.FRAME_TAG will contain the received frame tag.
- RX_FRAME_TAG_UDATA.USER_DATA will contain the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag will be set in the RX_EVT_STS register.

NOTE: If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The follow errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

32.4.3.3.1 Receiving Frames with DMA

The FSI receiver can continuously receive data and move it from the receiver buffer with the DMA. A DMA trigger will be generated every time a data frame has been received. This is concurrent with the FRAME_DONE signal that sets the RX_EVT_STS.FRAME_DONE flag. In order to receive continuous data with the DMA, some configurations need to be made on the receiver.

First, set RX_DMA_CTRL.DMA_EVT_EN to 1. This will allow the DMA trigger to propagate to the DMA module. The receiver is now able to trigger a DMA event upon the reception of a data frame.

The DMA must also be configured properly for the FSI to receive the data. One possible solution for using the receiver to continuously feed the DMA is show below:

- Set up two DMA channels to be triggered by the FSI Receiver DMA Trigger.
- Configure one DMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next DMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, ensure the DMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the DMA channel which is handling the data buffer, execute before the DMA channel handling the received tag and user data.

32.4.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event will be triggered which can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter which is reset and restarted upon the successful reception of a ping frame. The watchdog counter will be incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting RX_PING_WD_CTRL.PING_WD_RST to 1 and then subsequently clearing it to 0.
2. Set RX_OPER_CTRL.PING_WD_RST_MODE to the desired watchdog reset event, either 0 for ping frames only, or 1 for any frame.
3. Set RX_PING_WD_REF to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting RX_PING_WD_CTRL.PING_EN to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the RX_PING_WD_CNT value reaches the value programmed in RX_PING_WD_REF, the RX_EVT_STS.PING_WD_TO flag will be set. If configured, and interrupt can be generated on this event.

32.4.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration that it takes for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog will be triggered which can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting RX_FRAME_WD_CTRL. FRAME_WD_CNT_RST to 1 and then subsequently clearing it to 0.
2. Set RX_FRAME_WD_REF.FRAME_WD_REF to the maximum number of SYSCLK cycles expected to be in the longest frame that may be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting RX_FRAME_WD_CTRL.FRAME_WD_CNT_EN to 1.

The frame watchdog is now enabled and can detect a failed frame.

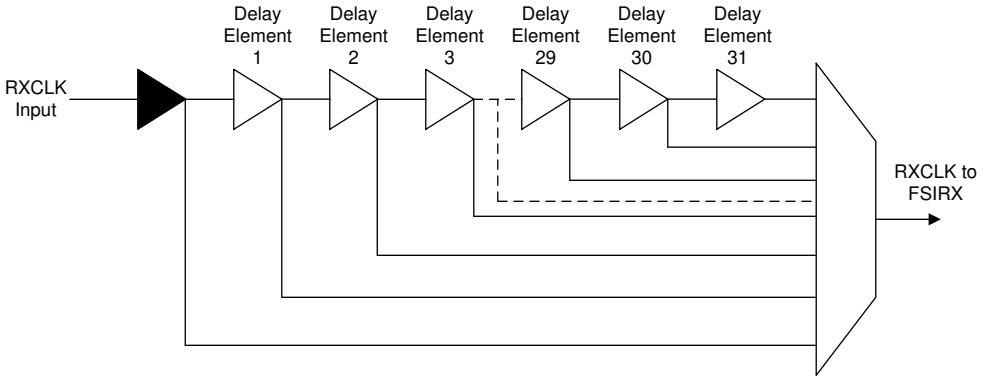
If the RX_FRAME_WD_CNT reaches the value programmed in RX_FRAME_WD_REF, the RX_EVT_STS.FRAME_WD_TO flag will be set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

32.4.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX_DLY_LINE_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values should only be adjusted while the FSIRX is held in soft reset, ensuring that there are no active transmissions during this process. Figure 32-8 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits will behave similarly.

Figure 32-8. Delay Line Control Circuit



For more information on skew compensation, please refer to http://www.ti.com/lit/an/spracj9/spracj9.pdf.

32.4.3.7 Buffer Management

The FSI receiver has a 16-word buffer into which the data is copied to when it has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX_BUF_PTR_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no guaranteed receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer guarantee which values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields may be ignored without adversely affecting the receiver capability. Additionally, the CURR_WORD_CNT will also be invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX_BUF_PTR_LOAD. This will force the receiver to start storing the received data starting at the indicated location in the buffer.

32.4.3.8 CRC Submodule

The receive module will automatically calculate the CRC on the incoming data. The received CRC value is placed into RX_CRC_INFO.RX_CRC. The CRC value calculated by hardware on the received data is placed into RX_CRC_INFO.CALC_CRC. These values are compared by hardware and will set RX_EVT_STS.CRC_ERROR if there is a mismatch. The receiver can generate an interrupt based on RX_EVT_STS.CRC_ERROR if enabled.

Since the CRC is only used in data frames, the values found in RX_CRC_INFO.RX_CRC and RX_CRC_INFO.CALC_CRC are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to Section 32.4.7.

If the transmitting module is sending a software-defined CRC value (FSITX.TX_OPER_CTRL_LO.SW_CRC = 1) the receiver module will trigger a CRC Error event if the received value does not match the hardware-calculated value. As this is an application level decision, the FSIRX can safely disregard the CRC error event. Application software will need to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field may have also been used as an application-specific value, not a CRC, the application can use the RX_CRC_INFO.RX_CRC as required. All CRC errors and flags can be ignored in this situation.

32.4.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (RX_FRAME_TAG_UDATA) register and receiver ping tag (RX_PING_TAG) register) have the Least Significant Bit is set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions which can be called depending on the tag value. A function pointer needs a 32-bit storage space and hence each successive pointer will be offset by 2. If the first pointer is at address x, then the second pointer will be at address x+2, the third at address x+4 and so on. By keeping the LSB 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

32.4.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver will receive data on every clock edge. While there are specific patterns which determine the a start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset in order to ensure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver may be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (RX_VIS_1.RX_CORE_STS) can be monitored to determine if it has entered into an error state requiring a soft reset in order to resume communication. Incorrect frame type and end of frame errors will always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout will always require a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. RX_CORE_STS can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also will not cause

RX_CORE_STS to be set. Similar to the frame watchdog, a corrupt receiver may not be the reason for the ping frame to have timed out. The transmitter may have gone offline and never sent a ping frame. Alternately, during idle time, a noise event may have occurred, thereby putting the receiver into a corrupt state. As the receiver will be able to detect this during the ping frame watchdog timeout interrupt handler, this type of event will not be lost and the application can act appropriately.

As the receiver is clocked by RXCLK, not SYSCLK, a noisy clock or data line may cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Ensure that the clock and data lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the data manual for this device. Failure to do so may cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application should check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun may warrant a soft reset in order to resynchronize with the local application software. Refer to Section 32.4.3.8 for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device should stop transmitting and begin a new synchronization phase.

32.4.3.11 Reset

The receiver module and its registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX_MASTER_CTRL.CORE_RST.

A module reset will cause the registers to be reset to their default state. After a module reset, the receiver module must be re-initialized, and the data link re-established.

32.4.4 Frame Format

The FSI module transmits and receives information in frames. Each frame will contain multiple phases where different information can be found. The number of phases as well as the total length of the frame will vary depending on the frame type being transmitted. Frames may be as short as 16 bits long for a ping or error frame or 288 bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown below. Each phase of the frame (such as start-of-frame, frame type, and so on) will be transmitted with the most significant bit first. Table 32-4 describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

Table 32-4. Basic Frame Structure

Idle state	Preamble	Start of Frame	Frame Type	User Data	Data Words	CRC byte	Frame Tag	End of Frame	Postamble	Idle state
	1111	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	1111	

The FSI also supports a SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to Section 32.4.11 for more information on how to configure and use the SPI compatibility mode.

NOTE: One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI .

32.4.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail below:

- **Idle State**
  During the idle state, the clock and data lines will be driven high, the inactive state.
- **Preamble**
  The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare it for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame**
  The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type**
  The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in Section 32.4.4.2. The transmitter must set the TX_FRAME_CTRL.FRAME_TYPE field before transmitting a frame. The received frame type is stored in the RX_FRAME_INFO.FRAME_TYPE.
- **User Data**
  The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX_FRAME_TAG_UDATA.USER_DATA. The received user data is stored in RX_FRAME_TAG_UDATA.USER_DATA.
- **Data**
  The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and will be placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames can be found in Section 32.4.4.2.3.
- **CRC Byte**
  The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX_OPER_CTRL_LO.SW_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag**
  The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX_FRAME_TAG_UDATA.FRAME_TAG bits for data frames. Ping frames use the tag defined in TX_PING_TAG.TAG. The receiver can access the received frame tag in RX_FRAME_TAG_UDATA.FRAME_TAG.
- **End of Frame**
  The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble**
  The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines will be driven high, their inactive state. This phase is not present in SPI compatibility mode.

32.4.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

Table 32-5 provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

Table 32-5. Frame Types and their 4-bit codes

Frame Type	4-bit Frame Code	Description
PING	0000	This is the ping frame which can be sent either by software or automatically by hardware.
ERROR	1111	This should be used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software is at liberty to use this for any purpose.
DATA_1_WORD	0100	1 word data packet (16 bits of data)
DATA_2_WORD	0101	2 word data packet (32 bits of data)
DATA_4_WORD	0110	4 word data packet (64 bits of data)
DATA_6_WORD	0111	6 word data packet (96 bits of data)
DATA_N_WORD	0011	N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules should have the same value programmed.
Reserved	0001, 0010, and 1000-1110	Reserved

32.4.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. Table 32-6 shows the structure of the ping frames.

Table 32-6. Ping Frame

Idle state	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle state
	1111	1001	0000	xxxx	0110	1111	

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to ensure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame which can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See Section 32.4.2.3.3 for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between it and the transmitter has been broken. See Section 32.4.3.4 for information on how the receiver handles ping frames.

32.4.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. Table 32-7 shows the structure of an error frame.

Table 32-7. Error Frame

Idle state	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle state
	1111	1001	1111	xxxx	0110	1111	

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX_FRAME_TAG_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX_FRAME_TAG_UDATA register and act on up to 16 different conditions.

32.4.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. Table 32-8 shows the general structure of data frames.

Table 32-8. Data Frame

Idle state	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle state
	1111	1001	0xxx	xxxx xxxx	1-16 words	xxxx xxxx	xxxx	0110	1111	

The frame type field will reflect the 4-bit code of the frame type. A list of frame types can be seen in Table 32-5. The number of the data words transmitted will be determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N_WORDS field of the transmitter's TX_FRAME_CTRL register and receiver's RX_OPER_CTRL register.

32.4.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits will be split between the data lines while the start of frame, frame type, frame tag, and end of frame fields will be identical and complete on each line. The user data, data, and CRC fields will be split between the data lines. Starting with the most significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the example below, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12…d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

Table 32-9. Multi-Lane Frame Format

Idle state	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle state
TXD0	1111	1001	0011	$u^7u^5u^3u^1$	$d^{15}d^{13}…d^1$	$c^7c^5c^3c^1$	xxxx	0110	1111	
TXD1	1111	1001	0011	$u^6u^4u^2u^0$	$d^{14}d^{12}…d^0$	$c^6c^4c^2c^0$	xxxx	0110	1111	

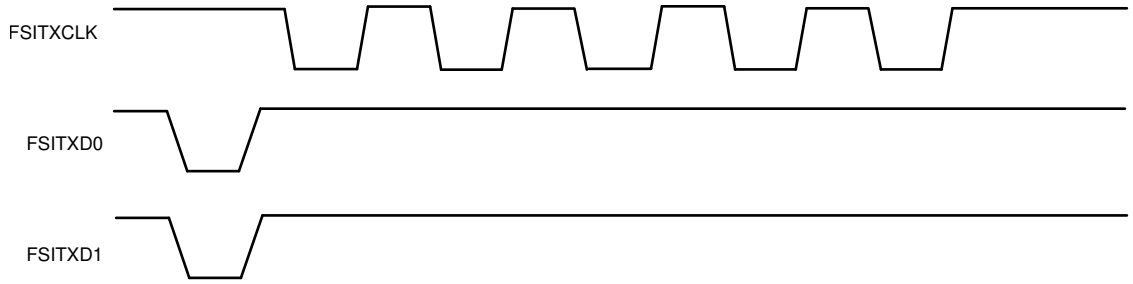
32.4.5 The Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before it can receive and decode frames. The receiver core has an asynchronous reset mechanism which will allow the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset will be released synchronous to the receive clock (RXCLK). Thus, the receiver will require five full clock pulses to be able to come out of reset. Sending the flush pattern will ensure that these clock edges are received and any subsequent frames sent to the receiver will be correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

Figure 32-9 shows a sample plot of the flush sequence.

Figure 32-9. Flush Sequence Signals



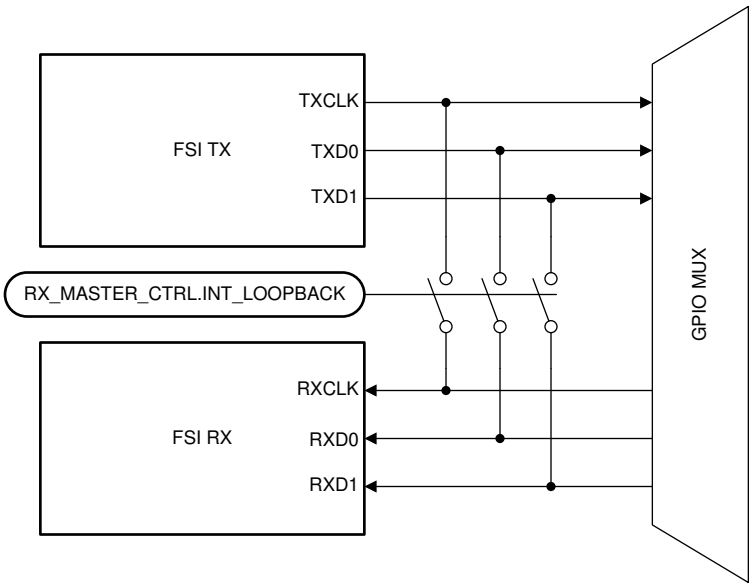
If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI will have the same effect as a flush sequence.

32.4.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting RX_MASTER_CTRL.INT_LOOPBACK to 1. Internal loopback will route the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter.

Figure 32-10 shows the signal connections with internal loopback.

Figure 32-10. FSI with Internal Loopback



In this device there are two FSI transmitter cores (A and B), and eight receiver cores (A, B, C, D, E, F, G, H). When using loopback mode, FSITXA can be used in the loopback mode with FSIRXA, FSIRXB, FSIRXC and FSIRXD. At the same time, FSITXB can be used in loopback mode with FSIRXE, FSIRXF, FSIRXG, and FSIRXH.

32.4.7 CRC Generation

The FSI uses CRC-8 with the polynomial 0x07 for the internal hardware CRC generation. This polynomial is also represented as x^8+x^2+x+1.

For example, for a 2-word data packet the following calculation would occur:

Data-1 = 0x4433

Data-0 = 0x2211

User Data = 0xAA

The CRC would be computed with the bytes being taken in the following order (first to last)

0xAA – Byte 0, User Data

0x11 – Byte 1, Data-0, Least significant byte

0x22 – Byte 2, Data-0, Most significant byte

0x33 – Byte 3, Data-1, Least significant byte

0x44 – Byte 4, Data-1, Most significant byte

32.4.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX_OPER_CTRL_HI.ECC_SEL to 1.
2. Write the data to the TX_ECC_DATA register as well as the transmit buffer.
3. Read TX_ECC_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX_ECC_VAL to TX_FRAME_TAG_UDATA.USER_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX_ECC_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX_FRAME_TAG_UDATA.USER_DATA to the RX_ECC_VAL register.
3. Read the RX_ECC_LOG register. This contains the result of the ECC computation using the RX_ECC_DATA and RX_ECC_VAL registers.
    1. If no ECC errors were detected, RX_ECC_LOG will be 0. The correct data will be available in RX_ECC_SEC_DATA.
    2. If a single bit error was detected, RX_ECC_LOG.SBE will be 1. The autocorrected data will be available in RX_ECC_SEC_DATA.
    3. If multiple bit errors occurred, RX_ECC_LOG.MBE will be set to 1. The data in RX_ECC_SEC_DATA is invalid and should not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame a allocate one of the data words to be the ECC value.

32.4.9 Tag Matching

The FSI receiver core has the capability of generating an interrupt when the received data or ping frame's tag matches the reference tag in RX_FRAME_TAG_CMP or RX_PING_TAG_CMP, respectively.

Each tag compare register allows the user to not only select a reference tag (TAG_REF) but also set up a mask (TAG_MASK) to ignore specified bits in the reference tag. In order for tag matching to be enabled, the CMP_EN bit must be set. When the tag compare is enabled and a successful match occurs, the PING_TAG_MATCH, the DATA_TAG_MATCH or the ERROR_TAG_MATCH in RX_EVT_ERR_STATUS will be set. The corresponding match register status can be cleared by writing to RX_EVT_ERR_CLEAR. Also, if it is required to set the match register status in software, the user must do so by writing to the RX_EVT_ERR_SET register.

The tag matching scheme is NOT a filtering scheme. Tag matching is only a notification scheme to alert the user when a specific tag is detected in a data or ping frame. Both RX_INTR_EVT_CTRL_1 and RX_INTR_EVT_CTRL_2 interrupts can be set up to generate an interrupt when a tag match event occurs.

Another feature used when tag matching is enabled, is the broadcast feature. The broadcast feature can be enabled by setting the BRDCST_EN in RX_FRAME_TAG_CMP or RX_PING_TAG_CMP. When broadcast mode is enabled, the third bit of the tag will be treated as a broadcast bit. If the received tag has it's third bit set, then it will be treated as a match regardless of the other tag bit comparisons. It is important to note that, a match caused by TAG_REF and TAG_MASK will also be considered a match.

It is important to reiterate that the tag matching scheme is not a filtering scheme. For example, if tag matching is enabled and a frame is received with a non matching tag, the frame is still saved in the buffer and the corresponding event status bits (FRAME_DONE, DATA_FRAME_RCVD etc.) will be set.

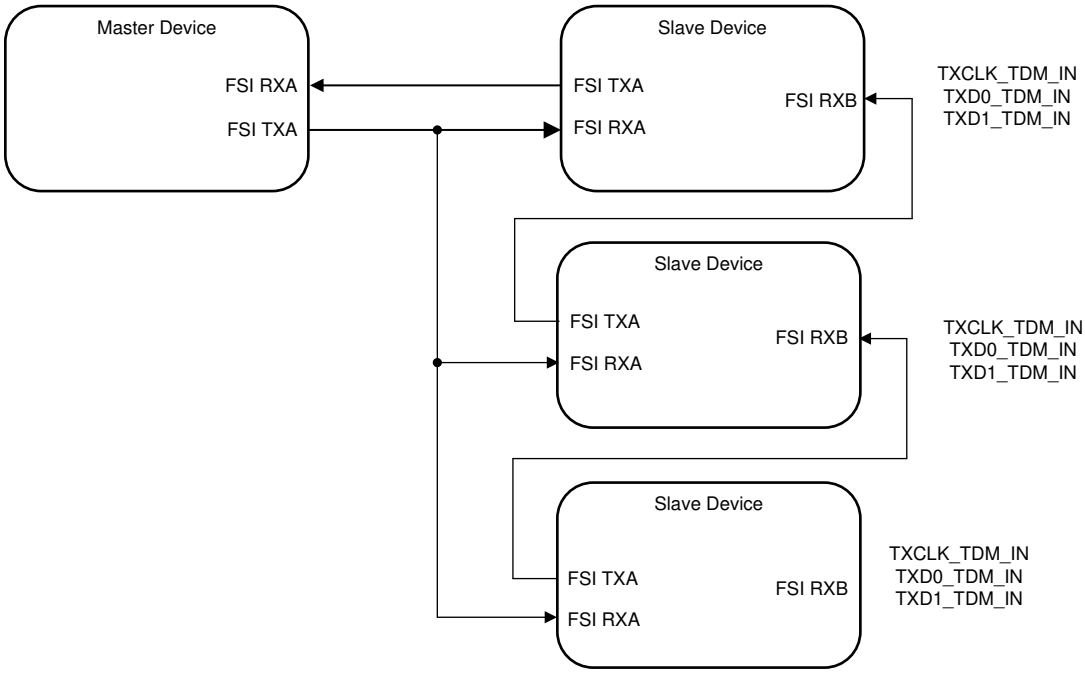
Tag matching is used in multi-slave configuration described in Section 32.4.10. However it can be used in single slave configurations as needed.

32.4.10 Multi-Slave Configurations

The FSI module in this device supports multi-slave configurations, whereas a single master can control multiple slave devices. In order to use the FSI module in a multi-slave configuration, the slave device must utilize both tag matching, and the CLB module.

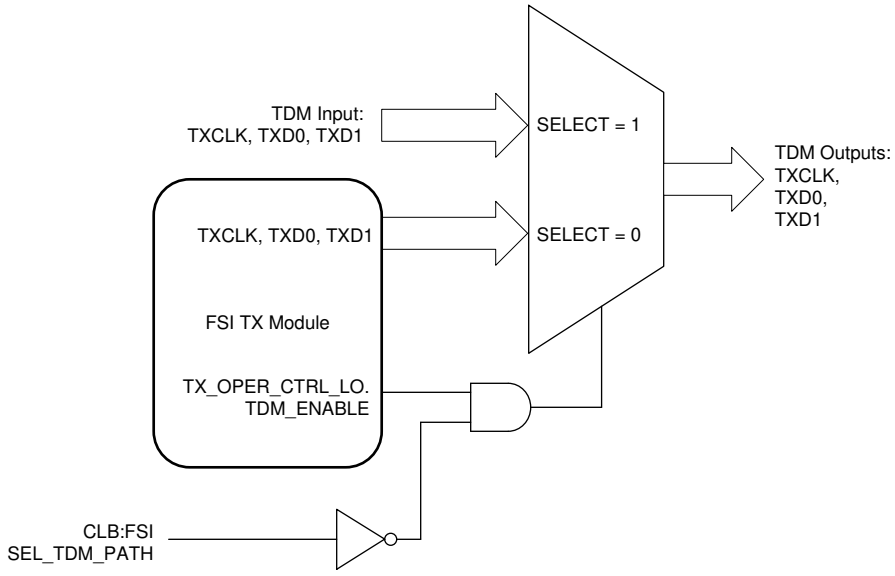
Multi-slave configuration is supported in the FSI module through time-division multiplexing. When TDM is enabled, each slave must also have tag matching enabled. The figure below shows a scheme where a single master is communicating with multiple slaves. All FSI receive modules in the slave devices are directly connected to the master device's transmit module. The transmit modules of the slave devices are chained serially such that each transmit module is connected to the next slave device and the last slave device's output connects to the master device's receive module. Each slave device will decide, based on the received frame's tag, whether to transmit their own data, or to enter bypass mode where they directly connect the previous slave device's transmit module to the next slave device. This is done by using the FSI transmit module's TMD_IN.

Figure 32-11. FSI Multi-Slave Configuration



When an FSI transmitter module is used in TDM mode, TXCLK_TDM_IN, TXD0_TDM_IN and TXD1_TDM_IN pins are used if the transmitter is required to enter bypass mode. In bypass mode, the FSI transmitter core will transmit the previous slave device's output. The figure below described how the FSI module operates when in multi-slave TDM mode.

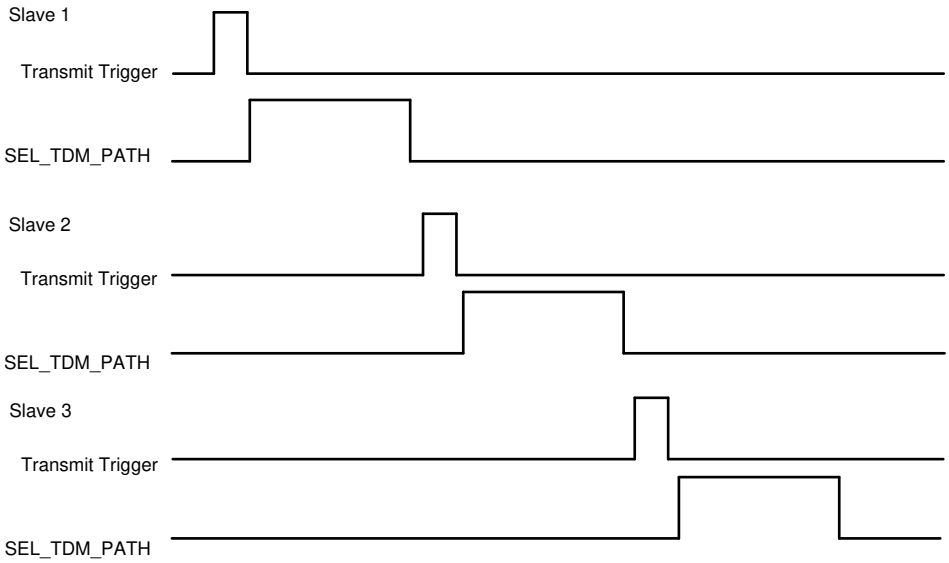
Figure 32-12. FSI Transmitter Multi-Slave Multiplexing



The SEL_TDM_PATH signal is sourced from the CLB module. The CLB module will also generate the transmit trigger for the FSI transmitter. The CLB module must be configured to decide when to generate the FSI transmit trigger based on the status of the data, ping, and frame tag match generated by the FSI receiver module. The FSITX module must be configured to transmit on an external trigger and the corresponding CLB trigger input must be selected. In a broadcast scenario (FSI tag match will notify all

slave devices that a match has occurred), the CLB module inside each slave will generate a trigger and SEL_TDM_PATH signal. The main key here is that the trigger and the SEL_TDM_PATH signal must be generated at a different time interval in a non-overlapping manner. The figure below shows an example of FSI transmit triggers and the multi-slave SEL_TDM_PATH signals generated by the CLB module of the slave devices in a broadcast scenario.

Figure 32-13. CLB Generated Signals for FSI Multi-Slave Configuration



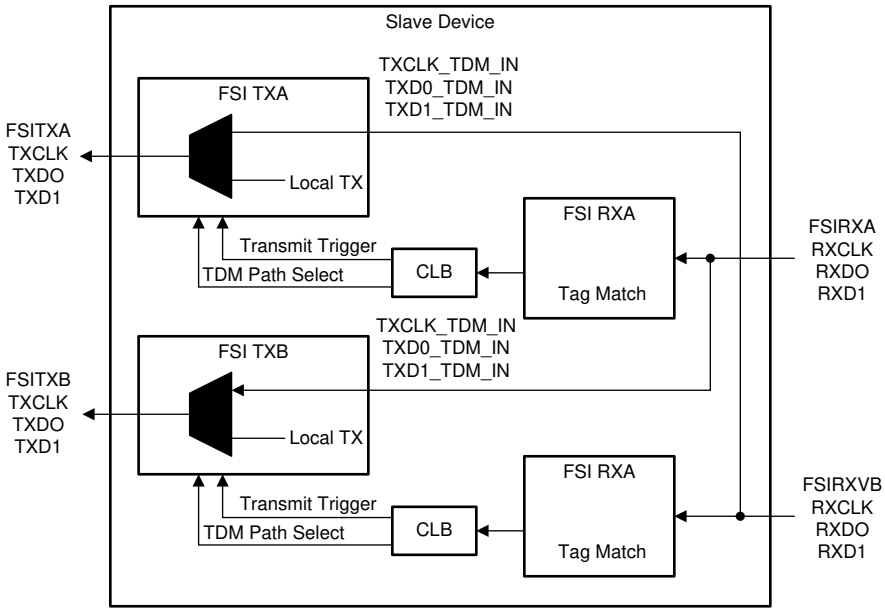
The TXCLK_TDM_IN, TXD0_TDM_IN and TXD1_TDM_IN for the FSI transmit modules available in this device are shown in the table below.

Table 32-10. FSI TDM Inputs

FSI Transmit Module	TXCLK_TDM_IN	TXD0_TDM_IN	TXD1_TDM_IN
FSITXA	FSIRXB RXCLK	FSIRXB RXD0	FSIRXB RXD1
FSITXB	FSIRXA RXCLK	FSIRXA RXD0	FSIRXA RXD1

The FSI transmit modules will be configured to use the external triggers generated by the CLB to initiate the transmission. Through appropriate configurations, the logic is designed to work assuming that only one TDM trigger will be generated until the transmission is completed. In the case where there is another trigger before the current transmission is competed, an error will be flagged in the TX_EVT_ERR_STATUS register. The figure below shows the connections between CLB, FSITX and FSIRX modules.

Figure 32-14. FSI and CLB Multi-Slave Connections



In Figure 32-11 the master device is connected to three slave devices. The master device uses FSITXA to transmit frames to the three slave devices. Each slave device will receive every frame, using their FSIRXA. The slave devices are chained together using their FSITXA output and FSIRXB inputs (configured as FSITXA TDM input). When a slave device receives a frame using its FSIRXA, it will check the tag of the frame to see if the tag matches the specified reference value in its tag compare register. When a match does occur, the CLB module will configure the FSITXA of the slave to select the local FSITXA outputs as the source for the output pins. However, if a match does not occur, the FSITXA of the slave device will be configured to enter bypass mode. There, it will select the FSITXA TDM inputs (which is FSIRXB) to be passed on to the output pins.

In this case when a frame is transmitted by the master, and the frame tag is matched only in one of the slave devices, all other devices with non-matching tags will enter bypass mode to allow the master to receive frames from the chosen slave device.

32.4.11 SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode follow:

- Data will transmit on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 will be driven like an active-low, chip-select signal. The signal will be low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks will be transmitted. All signals return to the IDLE state after the frame phase is finished.
- It is not possible to transmit in the SPI slave configuration because the FSI TXCLK cannot take an external clock source.

Table 32-11 lists the frame structure of the SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI slave, the standard SPI must encode the transmission to be sent.

Table 32-11. SPI Compatibility Frame Structure

Idle state	Start of Frame	Frame Type	User Data	Data Words	CRC byte[1]	Frame Tag	End of Frame	Idle state
	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	

(1) The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data would be arranged in the following manner. The example provided in Table 32-12 assumes a DATA_2_WORD frame has been sent.

Table 32-12. Contents of Data Received by a Standard SPI

SPI Data	Data Contents
SPI word 0	1001, 0100, 8-bit User Data
SPI word 1	Data word 1
SPI word 2	Data word 2
SPI word 3	8-bit CRC, 4-bit Frame Tag, 0110

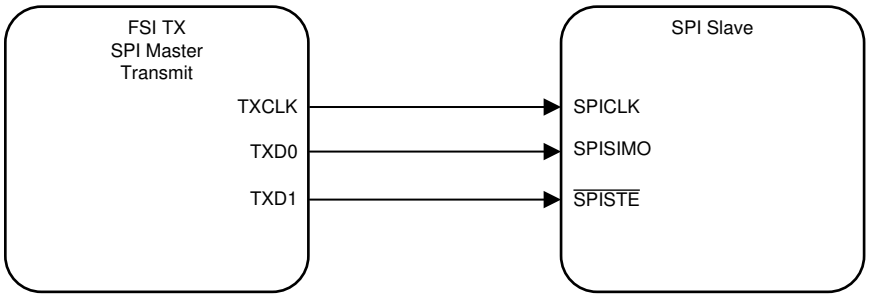
32.4.11.1 Available SPI Modes

There are a few wiring schemes available for the FSI to use when communicating with a SPI module.

32.4.11.1.1 FSITX as SPI Master, Transmit Only

The FSITX can operate as an independent SPI Master module. In this condition, TXCLK will be connected to SPICLK, TXD0 will be connected to SPISIMO, and TXD1 will be connected to $\overline{\text{SPISTE}}$, the chip select.

Figure 32-15. FSITX as SPI Master, Transmit Only



When the FSI is a SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver will require some software to act upon this information.

Table 32-13. FSI as Master Transmitter, SPI as Slave Receiver

Capability	Availability	Comment
Framing checks on the data frames	Yes	Can be implemented in software on the SPI receiver.
Ability to detect line breaks	Yes	Can be implemented in software on the SPI receiver but will require additional software overhead such as a timer, or watchdog.
CRC check	Yes	Can be implemented in software on the SPI receiver. For devices which have VCU, this will be more efficient.

Table 32-13. FSI as Master Transmitter, SPI as Slave Receiver (continued)

Capability	Availability	Comment
ECC on data	Yes	Can be implemented in software in the SPI receiver
Detection of abruptly terminated frames	No	
Double edge data rate	No	
Recovery from glitches on signal lines between frames	No	
Skew adjustment on signal lines	No	

32.4.11.1.1.1 Initialization

To configure the FSITX module to be a SPI master for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX_OPER_CTRL_LO.SPI_MODE to 1. This will enable the SPI clocking scheme and signaling structure.

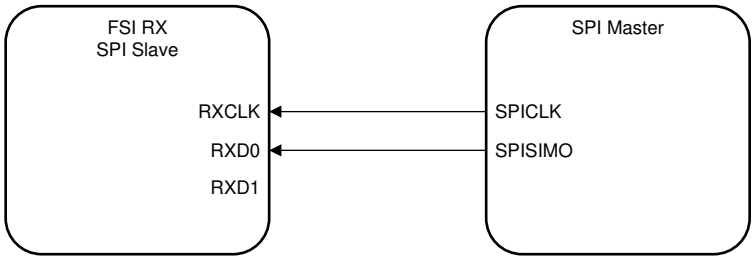
32.4.11.1.1.2 Operation

The operation of the FSITX module in SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to Section 32.4.2 for more information on each of these features.

32.4.11.1.2 FSIRX as SPI Slave, Receive Only

The FSIRX can operate as an independent SPI slave module. In the usage, RXCLK will be connected to SPICLK, and RXD0 will be connected to SPISIMO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX will respond to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence will be required to resynchronize the FSIRX module with the Master.

Figure 32-16. FSIRX as SPI Slave, Receive Only



When the FSI is a SPI receiver communicating with a SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

Table 32-14. SPI as master transmitter, FSI as slave receiver

Capability	Availability	Comment
Framing checks on the data frames	Yes	Standard on FSI
Ability to detect line breaks	Yes	Can be implemented in software in the SPI transmitter. But will have to use some timer or watchdog in the transmitting SPI device
CRC check	Yes	Can be implemented in software in the SPI transmitter.
ECC on data	Yes	Can be implemented in software in the SPI transmitter.

Table 32-14. SPI as master transmitter, FSI as slave receiver (continued)

Capability	Availability	Comment
Detection of abruptly terminated frames	Yes	This is accomplished with the FSI setting up the frame watchdog counter.
Double edge data rate	No	
Recovery from glitches on signal lines between frames	Yes	Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame will discard the effects of these glitches and will cause the receiver to resynchronize when the real “start-of-frame” pattern is seen. So, the ability to reject glitches in between frames is hence very high.
Skew adjustment on signal lines	Yes	The FSI receiver has the ability to add delays to the incoming signal lines.

32.4.11.1.2.1 Initialization

To configure the FSIRX module to be a SPI slave for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set RX_OPER_CTRL.SPI_MODE to 1. This will enable the SPI clocking scheme and signaling structure.

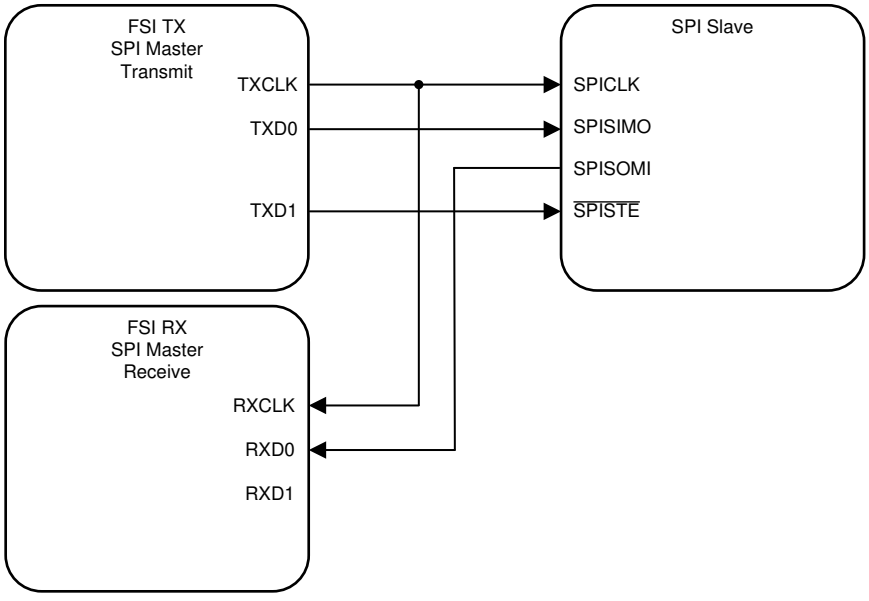
32.4.11.1.2.2 Operation

The operation of the FSIRX module in SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to Section 32.4.3 for more information on each of these features.

32.4.11.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Master

In this configuration, the FSITX is the clock master. The FSITX module will drive TXCLK (SPICLK), TXD0 (SPISIMO), and TXD1 (SPISTE/chip select), to the SPI slave. The SPISOMI signal will be connected back to the RXD0 signal. RXCLK can be fed either internally using the internal SPI pairing feature or wired externally, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX could also be thought of as an additional SPI slave. Some software logic will be required in order for the FSI to emulate a SPI master fully.

Figure 32-17. FSITX and FSIRX as SPI Master, Full Duplex



32.4.11.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI master operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set their respective SPI_MODE bits. This will enabled the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX_MASTER_CTRL.SPI_PAIRING to 1. This will internally connect TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK may be reallocated to other application requirements.

If the application requires an external clock loopback, ensure that TXCLK is connected to RXCLK. This may be required if the SPI Slave is across an isolation barrier and there is latency between TXCLK being launched and SPISOMI data being received on RXD0.

32.4.11.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI master module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

32.5 Programmer's Model

This section describes various operational sequences and features for the FSI.

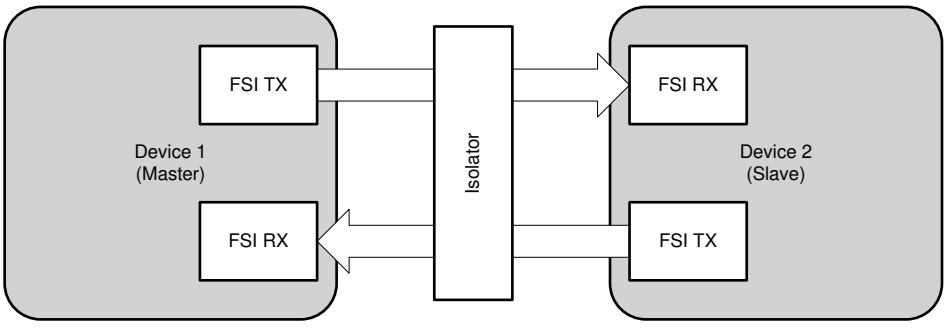
32.5.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules may exchange data. Since the receiver will accept data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example walks through a suggested approach for establishing a clean communication link on two separate devices that may power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to ensure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 32-18 shows the connection of the devices in this example. While there is no true concept of a master or a slave node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

Figure 32-18. Point to Point Connection



Device 1 is the master node; it will be the driver of the initialization sequence. Device 2 is the slave node; it will respond to the master's commands. In this example, as well as in a real world use-case, neither the master nor the slave may know precisely when the other is ready to receive communication.

Sample sequences for both the master device and slave device are provided below:

32.5.1.1 Establishing the Communication Link From the Master

The following sequence is an example of how the master node can establish the communication link with the slave without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
   - Send the flush sequence.
   - Send a ping frame with the frame tag 0000.
   - Wait for some time. (determined by application)
   - If the FSIRX has received a valid ping frame, continue; else iterate the loop again.
   - If the received ping frame tag was 0001, continue; else iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point both the master transmit and receive channels have successfully received a frame from their slave counterparts. The link has been established and standard application communication may begin.

32.5.1.2 Establishing the Communication Link from the Slave

The following sequence is an example of how the slave node can establish the communication link with the master without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else return to step 4.
6. If the received frame tag was 0000, continue; else discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else return to step 4.
11. If the received ping frame tag was 0001, continue; else if the received frame tag was 0000, return to step 9. This can happen if a second ping frame was already in transit before receiving the slave's response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from their master counterparts. The link has been established and regular communication may now proceed. The application may configure periodic ping frames from the transmitter, initialize the receiver's ping and frame watchdogs and begin the communication required by the application.

32.5.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a master register lock. These protections ensure that no spurious writes or unintentional modifications to these registers are accepted. Refer to the Section 32.6 for the register and bit descriptions to find the list of registers with write protections available.

EALLOW Protection

EALLOW is a device-level register protection; refer to for more information on EALLOW. For those registers with EALLOW protection, the EALLOW bit should be set before modifying the register. The application should then clear the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. In order to write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX_MASTER_CTRL.CORE_RST must be set. To do this, write 0xA501 to TX_MASTER_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE_RESET bit. Refer to the register descriptions for more information on which registers have write keys added.

Control Register Lock Protection

There also exists a master lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the register descriptions section. The control register lock will prevent any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX_LOCK_CTRL and TX_LOCK_CTRL for the receiver and transmitter respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV_CFG_REGS.SOFTPRESx) for the FSI module. Refer to Section 32.4.2.7 for more information on SYSRSn.

32.5.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores will always be in free running mode. CPU halts will not have any effect on the operation of the FSI. However, reads of registers and data buffers by the debugger will not affect any flags, or status of the data buffers.

If the user wishes to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

32.6 FSI Registers

This section describes the Fast Serial Interface Registers. The FSI module contains two distinct sets of registers. One for the FSI receiver, and another for the FSI transmitter.

32.6.1 FSI Base Addresses

Table 32-15. FSI Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
FsiTxaRegs	FSI_TX_REGS	FSITXA_BASE	0x0000_6600	YES	YES	YES	YES	YES
FsiRxaRegs	FSI_RX_REGS	FSIRXA_BASE	0x0000_6680	YES	YES	YES	YES	YES
FsiTxbRegs	FSI_TX_REGS	FSITXB_BASE	0x0000_6700	YES	YES	YES	YES	YES
FsiRxbRegs	FSI_RX_REGS	FSIRXB_BASE	0x0000_6780	YES	YES	YES	YES	YES
FsiRxcRegs	FSI_RX_REGS	FSIRXC_BASE	0x0000_6880	YES	YES	YES	YES	YES
FsiRxdRegs	FSI_RX_REGS	FSIRXD_BASE	0x0000_6980	YES	YES	YES	YES	YES
FsiRxeRegs	FSI_RX_REGS	FSIRXE_BASE	0x0000_6A80	YES	YES	YES	YES	YES
FsiRxfRegs	FSI_RX_REGS	FSIRXF_BASE	0x0000_6B80	YES	YES	YES	YES	YES
FsiRxgRegs	FSI_RX_REGS	FSIRXG_BASE	0x0000_6C80	YES	YES	YES	YES	YES
FsiRxhRegs	FSI_RX_REGS	FSIRXH_BASE	0x0000_6D80	YES	YES	YES	YES	YES

32.6.2 FSI_RX_REGS Registers

Table 32-16 lists the FSI_RX_REGS registers. All register offset addresses not listed in Table 32-16 should be considered as reserved locations and the register contents should not be modified.

Table 32-16. FSI_RX_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	RX_MASTER_CTRL	Receive master control register	EALLOW	Go
4h	RX_OPER_CTRL	Receive operation control register	EALLOW and LOCK	Go
6h	RX_FRAME_INFO	Receive frame control register		Go
7h	RX_FRAME_TAG_UDATA	Receive frame tag and user data register		Go
8h	RX_DMA_CTRL	Receive DMA event control register	EALLOW and LOCK	Go
Ah	RX_EVT_STS	Receive event and error status flag register		Go
Bh	RX_CRC_INFO	Receive CRC info of received and computed CRC		Go
Ch	RX_EVT_CLR	Receive event and error clear register	EALLOW	Go
Dh	RX_EVT_FRC	Receive event and error flag force register	EALLOW	Go
Eh	RX_BUF_PTR_LOAD	Receive buffer pointer load register	EALLOW	Go
Fh	RX_BUF_PTR_STS	Receive buffer pointer status register		Go
10h	RX_FRAME_WD_CTRL	Receive frame watchdog control register	EALLOW and LOCK	Go
12h	RX_FRAME_WD_REF	Receive frame watchdog counter reference	EALLOW and LOCK	Go
14h	RX_FRAME_WD_CNT	Receive frame watchdog current count		Go
16h	RX_PING_WD_CTRL	Receive ping watchdog control register	EALLOW and LOCK	Go
17h	RX_PING_TAG	Receive ping tag register		Go
18h	RX_PING_WD_REF	Receive ping watchdog counter reference	EALLOW and LOCK	Go
1Ah	RX_PING_WD_CNT	Receive pingwatchdog current count		Go
1Ch	RX_INT1_CTRL	Receive interrupt control register for RX_INT1	EALLOW and LOCK	Go
1Dh	RX_INT2_CTRL	Receive interrupt control register for RX_INT2	EALLOW and LOCK	Go
1Eh	RX_LOCK_CTRL	Receive lock control register		Go
20h	RX_ECC_DATA	Receive ECC data register		Go
22h	RX_ECC_VAL	Receive ECC value register		Go
24h	RX_ECC_SEC_DATA	Receive ECC corrected data register		Go
26h	RX_ECC_LOG	Receive ECC log and status register		Go
28h	RX_FRAME_TAG_CMP	Receive frame tag compare register	EALLOW and LOCK	Go
29h	RX_PING_TAG_CMP	Receive ping tag compare register	EALLOW and LOCK	Go
30h	RX_DLYLINE_CTRL	Receive delay line control register	EALLOW and LOCK	Go
38h	RX_VIS_1	Receive debug visibility register 1		Go
40h + formula	RX_BUF_BASE_y	Base address for receive data buffer	EALLOW and LOCK	Go

Complex bit access types are encoded to fit into small table cells. Table 32-17 shows the codes that are used for access types in this section.

Table 32-17. FSI_RX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

32.6.2.1 RX_MASTER_CTRL Register (Offset = 0h) [reset = 0h]

RX_MASTER_CTRL is shown in Figure 32-19 and described in Table 32-18.

Return to the Summary Table.

Receive master control register

Figure 32-19. RX_MASTER_CTRL Register

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED					SPI_PAIRING	INT_LOOPBACK	CORE_RST
R-0h					R/W-0h	R/W-0h	R/W-0h

Table 32-18. RX_MASTER_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-3	RESERVED	R	0h	Reserved
2	SPI_PAIRING	R/W	0h	Clock Pairing for SPI-like Behavior Enable bit This bit enables the internal clock pairing with the FSI TX module. This feature internally connects the TXCLK to RXCLK allowing the FSI TX module, acting as a SPI master, to clock data into the receiver and out of the transmitter like a standard SPI module. This configuration is valid when the Module is in SPI mode only (RX_OPER_CTRL.SPI_MODE = 1) 0h (R/W) = SPI clock pairing is not enabled. 1h (R/W) = SPI clock pairing is enabled. The RXCLK will be internally connected to the TXCLK of the corresponding FSI module. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn
1	INT_LOOPBACK	R/W	0h	Internal Loopback Enable bit This bit enables the internal loopback functionality of the FSI receiver. By enabling this bit, a mux will select the signals coming directly from the corresponding FSI transmitter module rather than from the pins. 0h (R/W) = Internal loopback is disabled. The FSI RX module will receive signals coming from the pins. 1h (R/W) = Internal loopback is enabled. The FSI RX module will receive signals from the directly from FSI TX module rather than the pins. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Receiver Master Core Reset bit This bit controls the receiver master core reset. In order to receive any frame, this bit must be cleared. 0h (R/W) = Receiver core is not in reset and can receive frames. 1h (R/W) = Receiver core is held in reset. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

32.6.2.2 RX_OPER_CTRL Register (Offset = 4h) [reset = 0h]

RX_OPER_CTRL is shown in Figure 32-20 and described in Table 32-19.

Return to the Summary Table.

Receive operation control register

Figure 32-20. RX_OPER_CTRL Register

15	14	13	12	11	10	9	8
RESERVED							PING_WD_RST_MODE
R-0h							R/W-0h
7	6	5	4	3	2	1	0
ECC_SEL	N_WORDS				SPI_MODE	DATA_WIDTH	
R/W-0h	R/W-0h				R/W-0h	R/W-0h	

Table 32-19. RX_OPER_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	PING_WD_RST_MODE	R/W	0h	Ping Watchdog Timeout Mode Select bit This bit selects the mode by which the ping watchdog counter is reset. The watchdog counter can be reset and restarted only by ping frames or by any received frame. 0h (R/W) = The ping watchdog counter will reset and restart only by ping frames. 1h (R/W) = The ping watchdog counter will reset and restart by any received frame. Reset type: SYSRSn
7	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between whether the ECC computation is done on 16-bit or 32-bit words. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
6-3	N_WORDS	R/W	0h	Number of Words to Receive This field defines the number of words which will be received in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the transmitter. Set this bitfield to be one less than the number of words to be received. This value is only applicable when the frame type received is DATA_N_WORD. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Enable bit This bit enables and disables the SPI compatibility mode of the FSI RX. The received data must be formatted as an FSI frame in order for the data to properly be received. SPI compatibility mode will allow FSI RX to receive data that is sent using SPI signal format. Refer to the applicable section in the FSI TRM chapter for more information. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn
1-0	DATA_WIDTH	R/W	0h	Receive Data Width Select bit These bits decide the number of data lines used for receiving data. 0h (R/W) = Data will be received on one data line, RXD0. 1h (R/W) = Data will be received on two data lines, RXD0 and RXD1. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

32.6.2.3 RX_FRAME_INFO Register (Offset = 6h) [reset = 0h]

RX_FRAME_INFO is shown in Figure 32-21 and described in Table 32-20.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3-0	FRAME_TYPE	R	0h	Received Frame Type This field indicates the type of frame that was successfully received last. 0000b (R/W) = A ping frame was received 0100b (R/W) = A DATA_1_WORD frame was received (16-bit data). 0101b (R/W) = A DATA_2_WORD frame was received (32-bit data). 0110b (R/W) = A DATA_4_WORD frame was received (64-bit data). 0111b (R/W) = A DATA_6_WORD frame was received (96-bit data). 0011b (R/W) = A DATA_N_WORD frame was received. The N_WORD field will determine the number of words (1 to 16) to be sent. The number of words received must equal the value programmed in RX_OPER_CTRL.N_WORDS. 1111b (R/W) = An error frame was received. This frame can be used during error conditions or any condition where the transmitter wants to signal the receiver for attention. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

32.6.2.4 RX_FRAME_TAG_UDATA Register (Offset = 7h) [reset = 0h]

RX_FRAME_TAG_UDATA is shown in Figure 32-22 and described in Table 32-21.

Return to the Summary Table.

14	ERROR_TAG_MATCH	R	0h	Error Tag Match Flag This bit indicates that an error frame was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched error frame received. 1h (R) = A tag-matched error frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
13	DATA_TAG_MATCH	R	0h	Data Tag Match Flag This bit indicates that a dataframe was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched data frame received. 1h (R) = A tag-matched data frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
12	PING_TAG_MATCH	R	0h	Ping Tag Match Flag This bit indicates that a ping frame was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched ping frame received. 1h (R) = A tag-matched ping frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
11	DATA_FRAME	R	0h	Data Frame Received Flag This bit indicates that an data frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No data frame has been received. 1h (R) = A data frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

Table 32-23. RX_EVT_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	FRAME_OVERRUN	R	0h	Frame Overrun Flag This bit indicates that a frame overrun condition has occured. This bit gets set to 1 when a new DATA/ERROR frame is received and the corresponding DATA_FRAME_RCVD/ERROR_FRAME_RCVD flag is still set to 1. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Frame overrun has not ocurred. 1h (R) = Frame overrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
9	PING_FRAME	R	0h	Ping Frame Received Flag This bit indicates that an ping frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No ping frame has been received. 1h (R) = A ping frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
8	ERR_FRAME	R	0h	Error Frame Received Flag This bit indicates that an error frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No error frame has been received. 1h (R) = An error frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
7	BUF_UNDERRUN	R	0h	Receive Buffer Underrun Flag This bit indicates that a buffer underrun condition has occured in the receive buffer. This will happen when software reads the buffer which is empty and has no valid data. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Receive Buffer Underrun has not ocurred. 1h (R) = Receive Buffer Underrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
6	FRAME_DONE	R	0h	Frame Done Flag This bit indicates that a frame has been successfully received without error. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No frame has been successfully received. 1h (R) = A frame has been successfully received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
5	BUF_OVERRUN	R	0h	Receive Buffer Overrun Flag This bit indicates that a buffer overrun condition has occured in the receive buffer. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Receive buffer overrun has not ocurred. 1h (R) = Receive buffer overrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

Table 32-23. RX_EVT_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	EOF_ERR	R	0h	End-of-Frame Error Flag This bit indicates that an invalid end-of-frame bit pattern has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Invalid end-of-frame has not been received. 1h (R) = Invalid end-of-frame has been received To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
3	TYPE_ERR	R	0h	Frame Type Error Flag This bit inditcates that an invalid frame type has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Invalid frame type has not been received. 1h (R) = Invalid frame type has been received To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
2	CRC_ERR	R	0h	CRC Error Flag This bit indicates that a CRC error has occured. A CRC error will be generated on a data frame where the received CRC and the computed CRC do not match. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = CRC error has not occured. 1h (R) = CRC error has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
1	FRAME_WD_TO	R	0h	Frame Watchdog Timeout Flag This bit indicates that the frame watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Frame watchdog timeout has not occured. 1h (R) = Frame watchdog timeout has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
0	PING_WD_TO	R	0h	Ping Watchdog Timeout Flag This bit indicates that the ping watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Ping watchdog timeout has not occured. 1h (R) = Ping watchdog timeout has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

32.6.2.7 RX_CRC_INFO Register (Offset = Bh) [reset = 0h]

RX_CRC_INFO is shown in Figure 32-25 and described in Table 32-24.

Return to the Summary Table.

Receive CRC info of received and computed CRC

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3	RX_CORE_STS	R	0h	Receiver Core Status bit This bit indicates the status of the receiver core. If this bit is set, the receiver should undergo a reset and subsequent resynchronization with the transmitter. This bit will be always be set when the receiver has detected and end of frame error or a frame type error. This bit can also be set if the receiver becomes corrupted due to noise on the signal lines. If the receiver has experienced a ping watchdog or frame watchdog timeout, this bit should be read to determine if the cause was due to a corrupt transaction, thus putting the receiver core into an unrecoverable state. Only a soft reset will reset the recevier core and thus reset this bit. 0h (R) The receiver core is operating normally. 1h (R) The receiver core has entered into an error state and should be reset. Reset type: SYSRSn
2-0	RESERVED	R	0h	Reserved

32.6.2.30 RX_BUF_BASE_y Register (Offset = 40h + formula) [reset = 0h]

RX_BUF_BASE_y is shown in Figure 32-48 and described in Table 32-47.

Return to the Summary Table.

Base address for receive data buffer

Offset = 40h + (y * 1h); where y = 0h to Fh

20h	TX_ECC_DATA	Transmit ECC data register		Go
22h	TX_ECC_VAL	Transmit ECC value register		Go
40h + formula	TX_BUF_BASE_y	Base address for transmit buffer		Go

Complex bit access types are encoded to fit into small table cells. Table 32-49 shows the codes that are used for access types in this section.

Table 32-49. FSI_TX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 32-49. FSI_TX_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

32.6.3.1 TX_MASTER_CTRL Register (Offset = 0h) [reset = 0h]

TX_MASTER_CTRL is shown in Figure 32-49 and described in Table 32-50.

Return to the Summary Table.

Table 32-50. TX_MASTER_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key In order to write to any bit in this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-2	RESERVED	R	0h	Reserved
1	FLUSH	R/W	0h	Flush Operation Start bit This bit will cause the transmitter to initiate a flush pattern of a single toggle on the TXD0 and TXD1 followed by five full cycles of TXCLK. This bit should be written only when the CORE_RST bit is 0 and the clock to the Transmitter core is turned on. 0h (R/W) = Clear this bit. 1h (R/W) = Setting this bit will Initiate flush sequence. To properly execute a flush sequence, Set FLUSH to 1, wait for five TXCLK cycles then clear FLUSH to 0. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. The software must keep this bit set to 1 for at least five TXCLK cycles before setting it back to 0. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Transmitter Master Core Reset bit This bit controls the transmitter master core reset. In order to send any frame, this bit must be cleared. 0h (R/W) = Transmitter core is not in reset and can transmit frames. 1h (R/W) = Transmitter core is held in reset. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

32.6.3.2 TX_CLK_CTRL Register (Offset = 2h) [reset = 0h]

TX_CLK_CTRL is shown in Figure 32-50 and described in Table 32-51.

Return to the Summary Table.

Table 32-54. TX_FRAME_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	START	R/W	0h	Start Transmission bit This bit will cause the FSI to start transmitting the next frame. 0h (R/W) = Writing a 0 to this bit will have no effect. 1h (R/W) = Start the next transmission. This bit will be cleared by hardware. Reset type: SYSRSn
14-8	RESERVED	R	0h	Reserved
7-4	N_WORDS	R/W	0h	Number of Words to be Transmitted This field defines the number of words which will be transmitted in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the receiver. Set this bitfield to be one less than the number of words to be transmitted. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
3-0	FRAME_TYPE	R/W	0h	Transmit Frame Type This field determines the type of frame that will be transmitted next. 0000b (R/W) = Ping Frame. This frame can be sent either by software or automatically by hardware. 0100b (R/W) = DATA_1_WORD Frame. One word data frame (16-bit data). 0101b (R/W) = DATA_2_WORD Frame. Two word data frame (32-bit data). 0110b (R/W) = DATA_4_WORD Frame. Four word data frame (64-bit data). 0111b (R/W) = DATA_6_WORD Frame. Six word data frame (96-bit data). 0011b (R/W) = DATA_N_WORD Frame. The N_WORDS field will determine the number of words (1 to 16) to be sent. Both the transmitter and receiver must have the same value programmed. 1111b (R/W) = Error Frame. This frame can be used during error conditions or any condition where the transmitter wants to notify the receiver of a high priorty status. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

32.6.3.6 TX_FRAME_TAG_UDATA Register (Offset = 7h) [reset = 0h]

TX_FRAME_TAG_UDATA is shown in Figure 32-54 and described in Table 32-55.

Return to the Summary Table.

Table 32-65. TX_EVT_STS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3	PING_TRIGGERED	R	0h	Ping Frame Triggered Flag Bit This bit indicates that a ping frame has been triggered. This bit is set by hardware when either the ping timer or an external trigger event have occured. Software can also force this bit to get set by writing to the TX_EVT_FRC register. 0h (R) = A ping frame has not been triggered. 1h (R) = A ping frame has been triggered by either the ping timer or external trigger. To clear this bit, write to the corresponding bit in the TX_EVT_CLR register. Reset type: SYSRSn
2	BUF_OVERRUN	R	0h	Buffer Overrun Flag Bit This bit inditcates that buffer overrun has occured.Software can also force this bit to get set by writing to the TX_EVT_FRC register. 0h (R) = Buffer Overrun has not occured. 1h (R) = Buffer Overrun has occured. To clear this bit, write to the corresponding bit in the TX_EVT_CLR register. Reset type: SYSRSn
1	BUF_UNDERRUN	R	0h	Buffer Underrun Flag Bit This bit inditcates that buffer underrun has occured.Software can also force this bit to get set by writing to the TX_EVT_FRC register. 0h (R) = Buffer Underrun has not occured. 1h (R) = Buffer Underrun has occured. To clear this bit, write to the corresponding bit in the TX_EVT_CLR register. Reset type: SYSRSn
0	FRAME_DONE	R	0h	Frame Done Flag Bit This bit inditcates a Frame Done condition. This bit is set by hardware when a frame transmission has been completed. Software can also force this bit to get set by writing to the TX_EVT_FRC register. 0h (R) = Frame Done condition has not occured. 1h (R) = Frame Done condition has occured. To clear this bit, write to the corresponding bit in the TX_EVT_CLR register. Reset type: SYSRSn

32.6.3.17 TX_EVT_CLR Register (Offset = 16h) [reset = 0h]

TX_EVT_CLR is shown in Figure 32-65 and described in Table 32-66.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3	PING_TRIGGERED	W	0h	Ping Frame Triggered Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Note: This bit may not always be cleared when writing to the corresponding TX_EVT_CLR bit. If PING_TIMEOUT MODE is configured to be 0, a hardware ping timeout may occur when another frame is actively being transmitted. In this case, if this bit still shows as 1 after the clear bit is written then the ping frame has been triggered but not serviced. This bit does not indicate that the ping frame has been completely sent, only that it has been triggered by the timeout event. Reset type: SYSRSn
2	BUF_OVERRUN	W	0h	Buffer Overrun Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Reset type: SYSRSn
1	BUF_UNDERRUN	W	0h	Buffer Underrun Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Reset type: SYSRSn
0	FRAME_DONE	W	0h	Frame Done Flag Clear bit This bit clears the corresponding bit in the TX_EVT_STS register. 0h (W) = Writing a 0 to this bit will have no effect. 1h (W) = Writing a 1 to this bit will clear the corresponding bit in the TX_EVT_STS register to 0. Reset type: SYSRSn

32.6.3.18 TX_EVT_FRC Register (Offset = 17h) [reset = 0h]

TX_EVT_FRC is shown in Figure 32-66 and described in Table 32-67.

Return to the Summary Table.

Inter-Integrated Circuit Module (I2C)

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1 to 8-bit data to/from the device through the I2C module. This guide assumes the reader is familiar with the I2C bus specification.

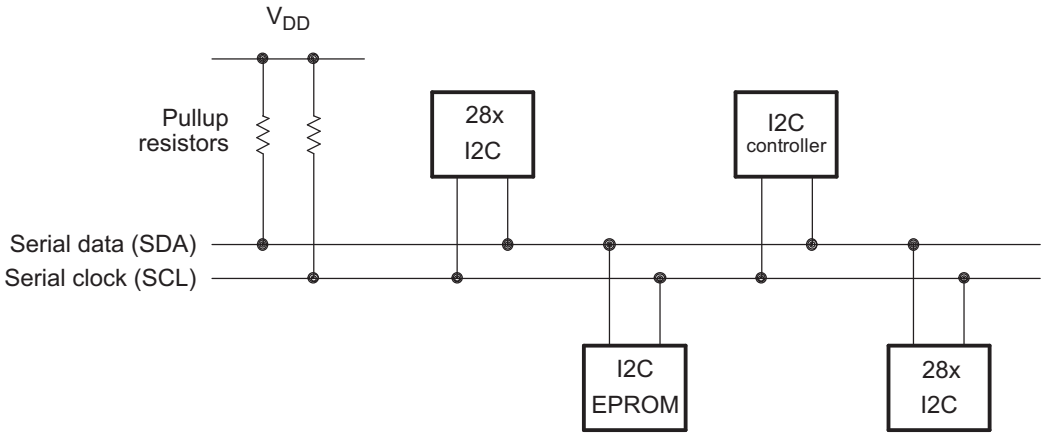
NOTE: A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this document. The number of bits in a data byte is selectable via the BC bits of the mode register, I2CMDR.

Topic **Page**

33.1 Introduction

The I2C module supports any slave or master I2C-compatible device. Figure 33-1 shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

Figure 33-1. Multiple I2C Modules Connected



33.1.1 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers
  - Support for multiple slave-transmitters and master-receivers
  - Combined master transmit/receive and receive/transmit mode
  - Data transfer rate from 10 kbps up to 400 kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the below events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as slave
  - I2Cx_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable/disable capability
- Free data format mode

33.1.2 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

33.1.3 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the master or the slave when performing data transfers. A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave. The I2C module supports the multi-master mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in Section 33.6. These two pins carry information between the 28x device and other devices connected to the I2C bus. The SDA and SCL pins both are bidirectional. They each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques: .

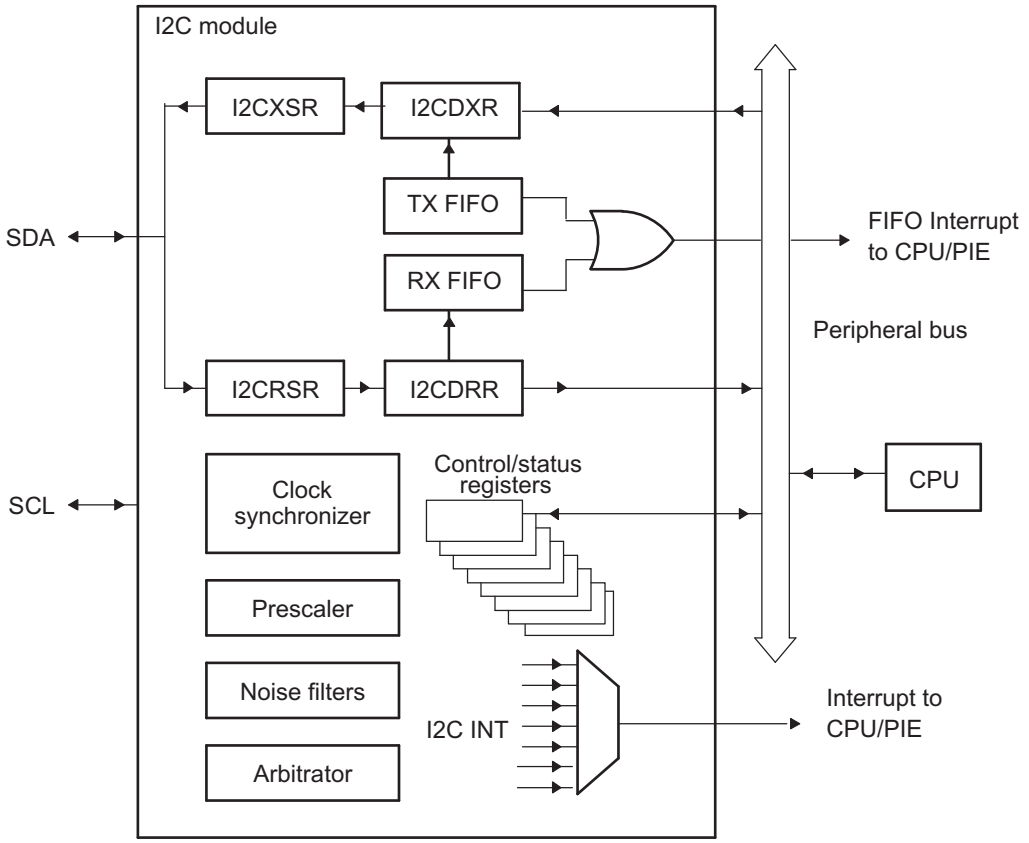
- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See Section 33.6 for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See *Registers* for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

Figure 33-2 shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

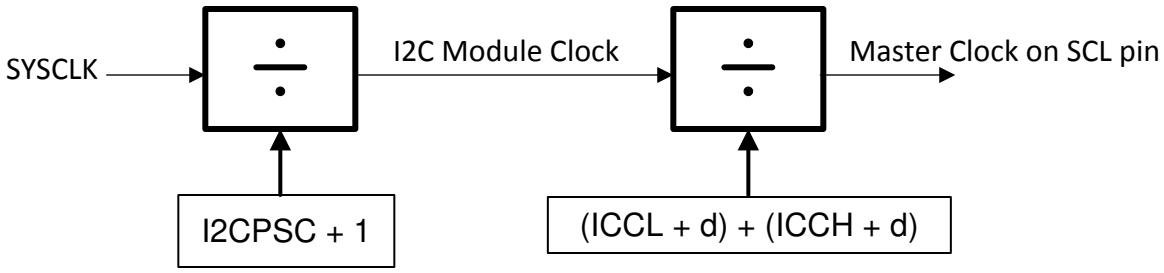
Figure 33-2. I2C Module Conceptual Block Diagram



33.1.4 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C master clock on the SCL pin. Figure 33-3 shows the clock generation diagram for I2C module.

Figure 33-3. Clocking Diagram for the I2C Module



To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)}$$

NOTE: To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7 - 12 MHz.

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

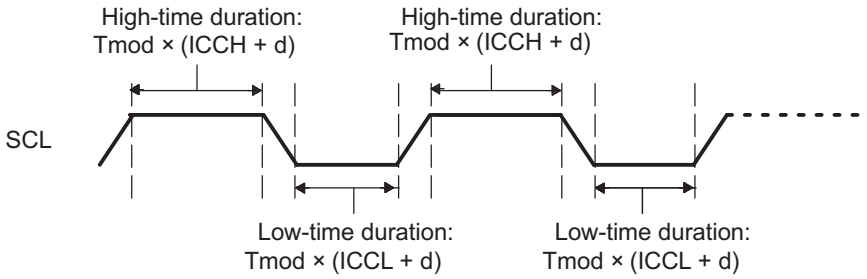
The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 33-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 33.1.5 for the master clock frequency equation.

33.1.5 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 33.1.4, when the I2C module is a master, the I2C module clock is divided down further to use as the master clock on the SCL pin. As shown in Figure 33-4, the shape of the master clock depends on two divide-down values:

- ICCL in I2CCLKL. For each master clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCKLH. For each master clock cycle, ICCH determines the amount of time the signal is high.

Figure 33-4. The Roles of the Clock Divide-Down Values (ICCL and ICCH)



33.1.5.1 Formula for the Master Clock Period

The master clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Master Clock period (Tmst)} = \frac{[\,(\text{ICCH} + d) + (\text{ICCL} + d)\,]}{\text{I2C Module Clock (Fmod)}}$$

where d depends on the divide-down value IPSC, as shown in Table 33-1. IPSC is described in the I2CPSC register.

Table 33-1. Dependency of Delay d on the Divide-Down Value IPSC

IPSC	d
0	7
1	6
Greater than 1	5

33.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

NOTE: The GPIO configuration register GPyODR must be set to normal mode when the I2C is used. The open-drain operation for I2C is managed by the I2C module

33.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

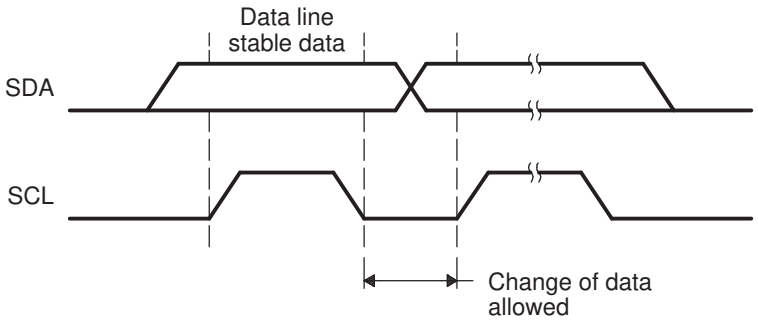
33.3.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{DD}. For details, see the data manual for your particular device.

33.3.2 Data Validity

The data on SDA must be stable during the high period of the clock (see Figure 33-5). The high or low state of the data line, SDA, should change only when the clock signal on SCL is low.

Figure 33-5. Bit Transfer on the I2C bus



33.3.3 Operating Modes

The I2C module has four basic operating modes to support data transfers as a master and as a slave. See Table 33-2 for the names and descriptions of the modes.

If the I2C module is a master, it begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. To receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, it begins as a slave-receiver and typically sends acknowledgment when it recognizes its slave address from a master. If the master will be sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

Table 33-2. Operating Modes of the I2C Module

Operating Mode	Description
Slave-receiver modes	The I2C module is a slave and receives data from a master. All slaves begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See section Section 35.4 for more details.

Table 33-2. Operating Modes of the I2C Module (continued)

Operating Mode	Description
Slave-transmitter mode	The I2C module is a slave and transmits data to a master.
	This mode can be entered only from the slave-receiver mode; the I2C module must first receive a command from the master. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its slave-transmitter mode if the slave address byte is the same as its own address (in I2COAR) and the master has transmitted R/$\overline{W}$ = 1. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See section Section 35.4 for more details.
Master-receiver mode	The I2C module is a master and receives data from a slave.
	This mode can be entered only from the master-transmitter mode; the I2C module must first transmit a command to the slave. When you are using any of the 7-bit/10-bit addressing formats, the I2C module enters its master-receiver mode after transmitting the slave address byte and R/$\overline{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.
Master-transmitter modes	The I2C module is a master and transmits control information and data to a slave.
	All masters begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.

To summarize, SCL will be held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Slave-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Slave-transmitter mode.

I2C slave nodes have to accept and provide data when the I2C master node requests it.

- To release SCL in slave-receiver mode, read data from I2CDRR.
- To release SCL in slave-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

Table 33-3. Master-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR

RM	STT	STP	Bus Activity(1)	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D.	START condition, slave address, n data bytes (n = value in I2CCNT)
0	1	1	S-A-D..(n)..D-P	START condition, slave address, n data bytes, STOP condition (n = value in I2CCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D.	Repeat mode transfer: START condition, slave address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

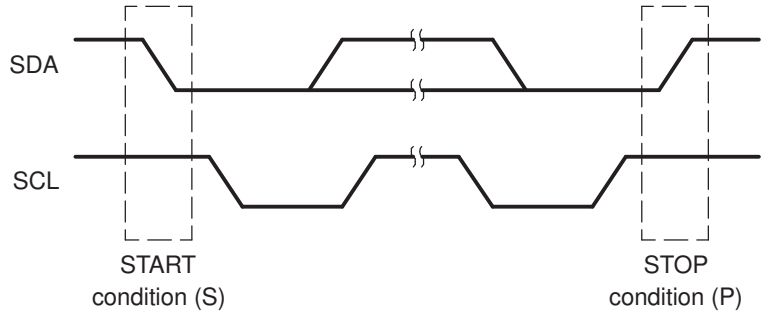
33.3.4 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a master on the I2C bus. As shown in Figure 33-6:

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.

- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

Figure 33-6. I2C Module START and STOP Conditions



After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and its bits (including MST, STT, and STP), see *Registers* Section 33.6.

The I2C peripheral cannot detect a START or STOP condition while it is in reset (IRS = 0). The BB bit will remain in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1) the BB bit will not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, users can ensure that at least one START or STOP condition will have occurred on the I2C bus and been captured by the BB bit. After this period, the BB bit will correctly reflect the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

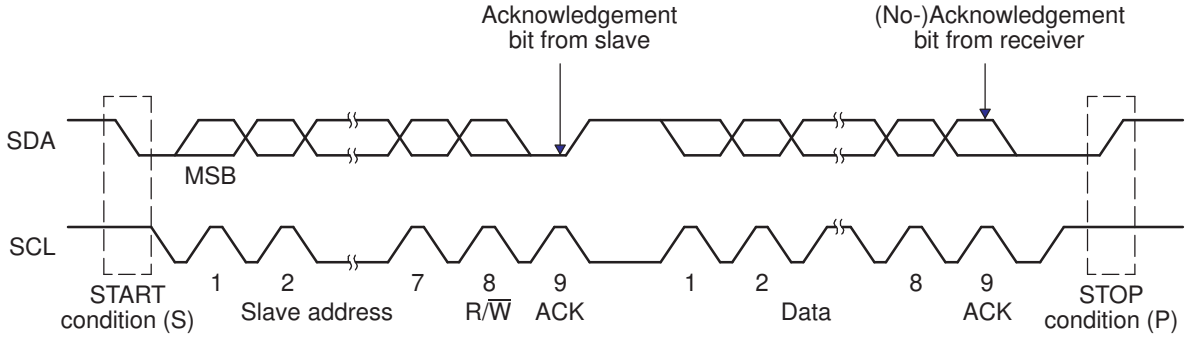
Not resetting the I2C peripheral in between transfers ensures that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

33.3.5 Serial Data Formats

Figure 33-7 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 33-7, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 33-7 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 33-8 through Figure 33-10 and described in the paragraphs that follow the figures.

NOTE: In Figure 33-7 through Figure 33-10, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

Figure 33-7. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)



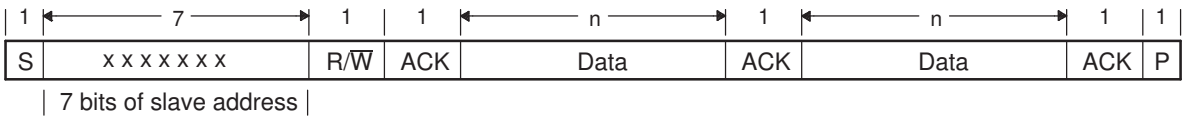
33.3.5.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 33-8), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/$\overline{W}$ bit. R/$\overline{W}$ determines the direction of the data:

- R/$\overline{W}$ = 0: The I2C master writes (transmits) data to the addressed slave. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/$\overline{W}$ = 1: The I2C master reads (receives) data from the slave. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

Figure 33-8. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)



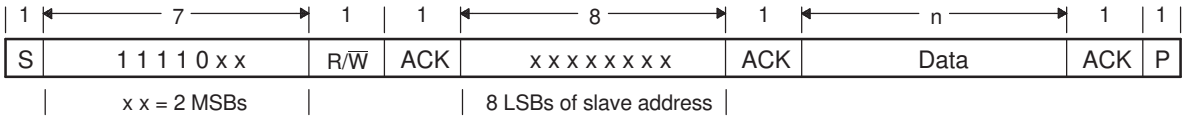
An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/$\overline{W}$ bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

33.3.5.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 33-9) is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and R/$\overline{W}$. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

Figure 33-9. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)

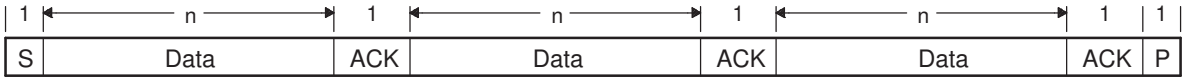


33.3.5.3 Free Data Format

The free data format can be enabled by setting I2CMDR. FDF = 1.

In this format (see Figure 33-10), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

Figure 33-10. I2C Module Free Data Format (FDF = 1 in I2CMDR)



NOTE: The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

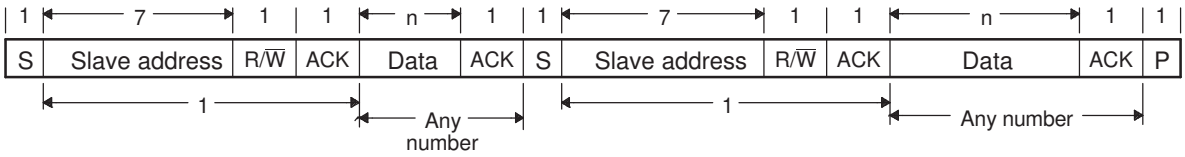
Table 33-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR

MST	FDF	I2C Module State	Function of TRX
0	0	In slave mode but not free data format mode	TRX is a don't care. Depending on the command from the master, the I2C module responds as a receiver or a transmitter.
0	1	In slave mode and free data format mode	The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module: TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	0	In master mode but not free data format mode	TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	1	In master mode and free data format mode	TRX = 0: The I2C module is a receiver. TRX = 1: The I2C module is a transmitter.

33.3.5.4 Using a Repeated START Condition

I2C master can communicate with multiple slave addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, and free data formats. Figure 33-11 shows a repeated START condition in the 7-bit addressing format.

Figure 33-11. Repeated START Condition (in This Case, 7-Bit Addressing Format)



NOTE: In Figure 33-11, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

33.3.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 33-5 summarizes the various ways you can tell the I2C module to send a NACK bit.

Table 33-5. Ways to Generate a NACK Bit

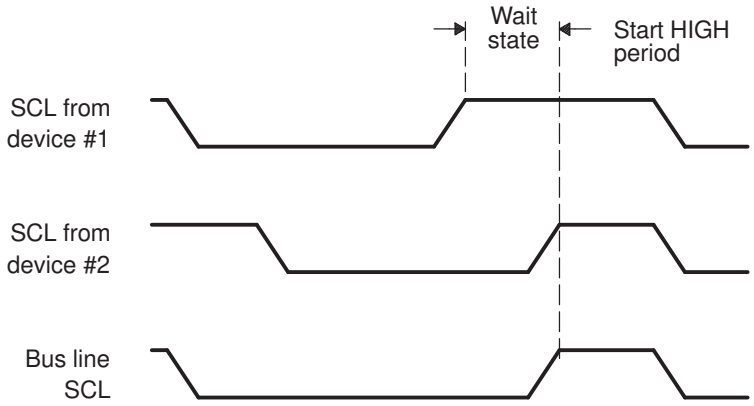
I2C Module Condition	NACK Bit Generation Options
Slave-receiver modes	• Allow an overrun condition (RSFULL = 1 in I2CSTR) • Reset the module (IRS = 0 in I2CMDR) • Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Master-receiver mode AND Repeat mode (RM = 1 in I2CMDR)	• Generate a STOP condition (STP = 1 in I2CMDR) • Reset the module (IRS = 0 in I2CMDR) • Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Master-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR)	• If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition • If STP = 0, make STP = 1 to generate a STOP condition • Reset the module (IRS = 0 in I2CMDR). = 1 to generate a STOP condition • Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive

33.3.7 Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. Figure 33-12 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL is held low by the device with the longest low period. The other devices that finish their low periods must wait for SCL to be released, before starting their high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

Figure 33-12. Synchronization of Two I2C Clock Generators During Arbitration



33.3.8 Arbitration

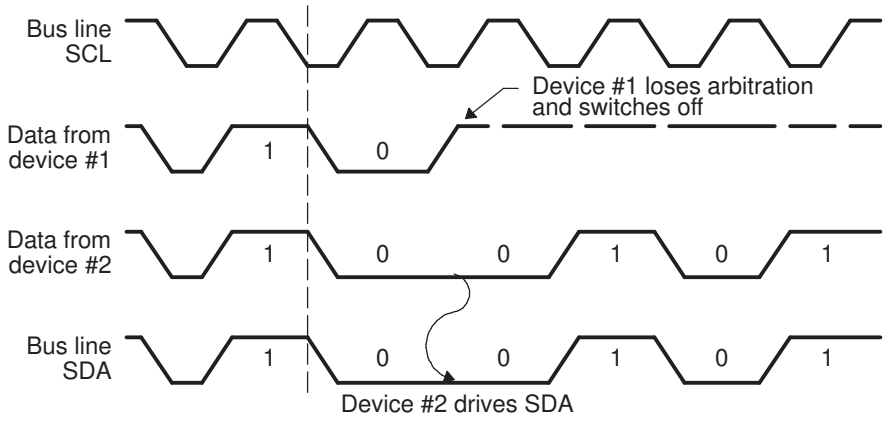
If two or more master-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 33-13 illustrates the arbitration procedure between two devices. The first master-transmitter that releases the SDA line high is overruled by another master-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, it switches to the slave-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Figure 33-13. Arbitration Procedure Between Two Master-Transmitters



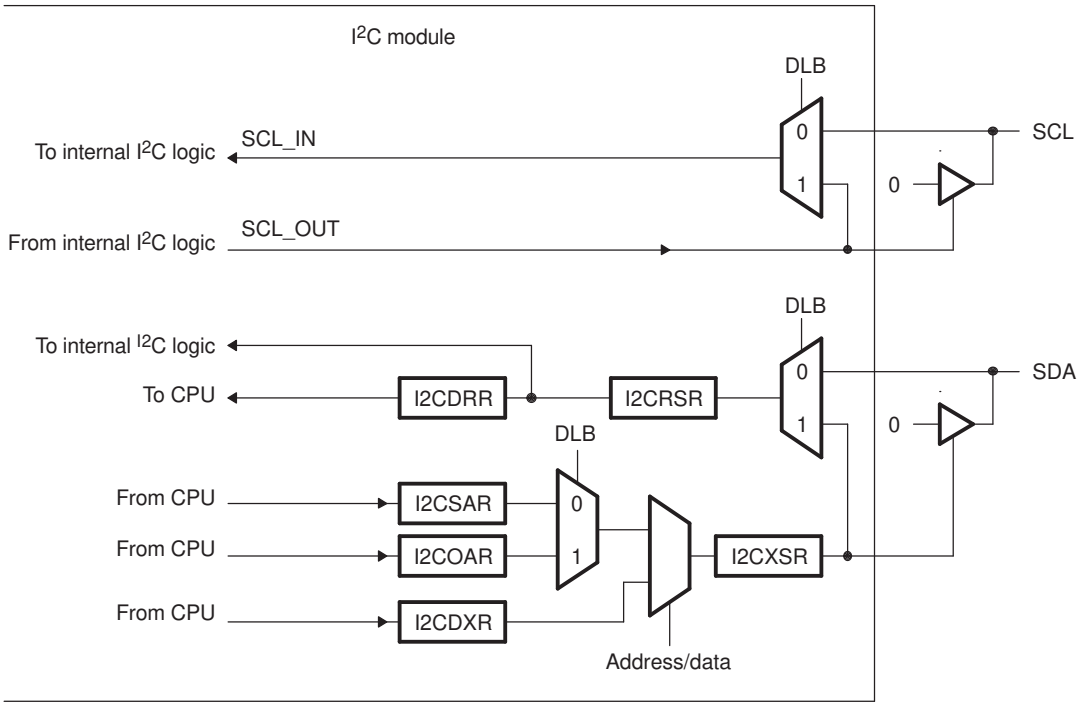
33.3.9 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

n = 8 * (SYSCLK) / (I2C module clock (Fmod))

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 33-14 shows the signal routing in digital loopback mode.

Figure 33-14. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit



NOTE: The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

33.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources which can trigger this interrupt are described in Section 33.4.1.
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources which can trigger this interrupt are described in Section 33.4.2

33.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in Table 33-6. As shown in Figure 33-15, all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, its flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if it is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A_ISR). The I2CINT1A_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A_ISR can branch to the appropriate subroutine.

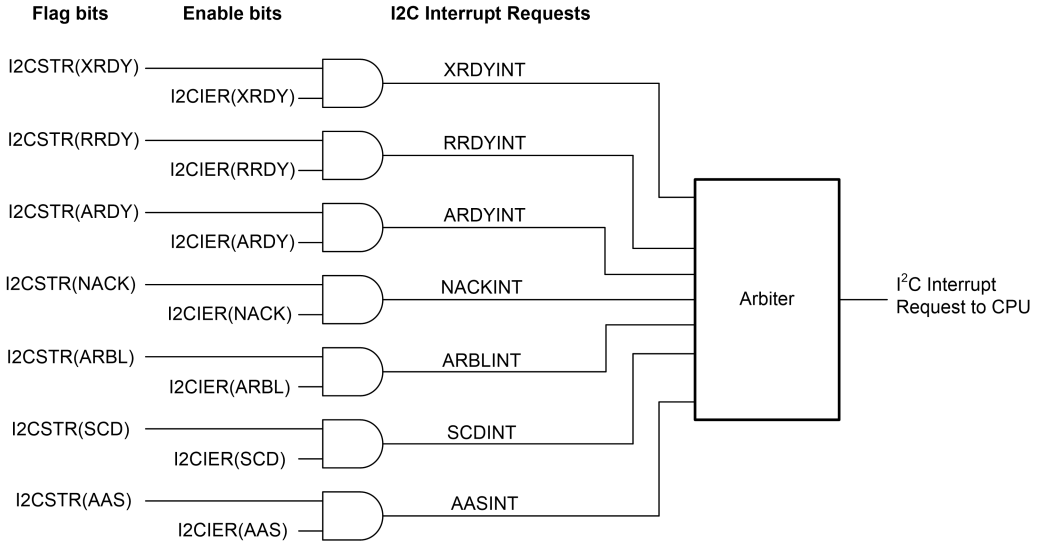
After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to it.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

Table 33-6. Descriptions of the Basic I2C Interrupt Requests

I2C Interrupt Request	Interrupt Source
XRDYINT	Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.
RRDYINT	Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT should not be used when in FIFO mode. Use the FIFO interrupts instead.
ARDYINT	Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR. As an alternative to using ARDYINT, the CPU can poll the ARDY bit.
NACKINT	No-acknowledgment condition: The I2C module is configured as a master-transmitter and did not received acknowledgment from the slave-receiver. As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.
ARBLINT	Arbitration-lost condition: The I2C module has lost an arbitration contest with another master-transmitter. As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.
SCDINT	Stop condition detected: A STOP condition was detected on the I2C bus. As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.
AASINT	Addressed as slave condition: The I2C has been addressed as a slave device by another master on the I2C bus. As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.

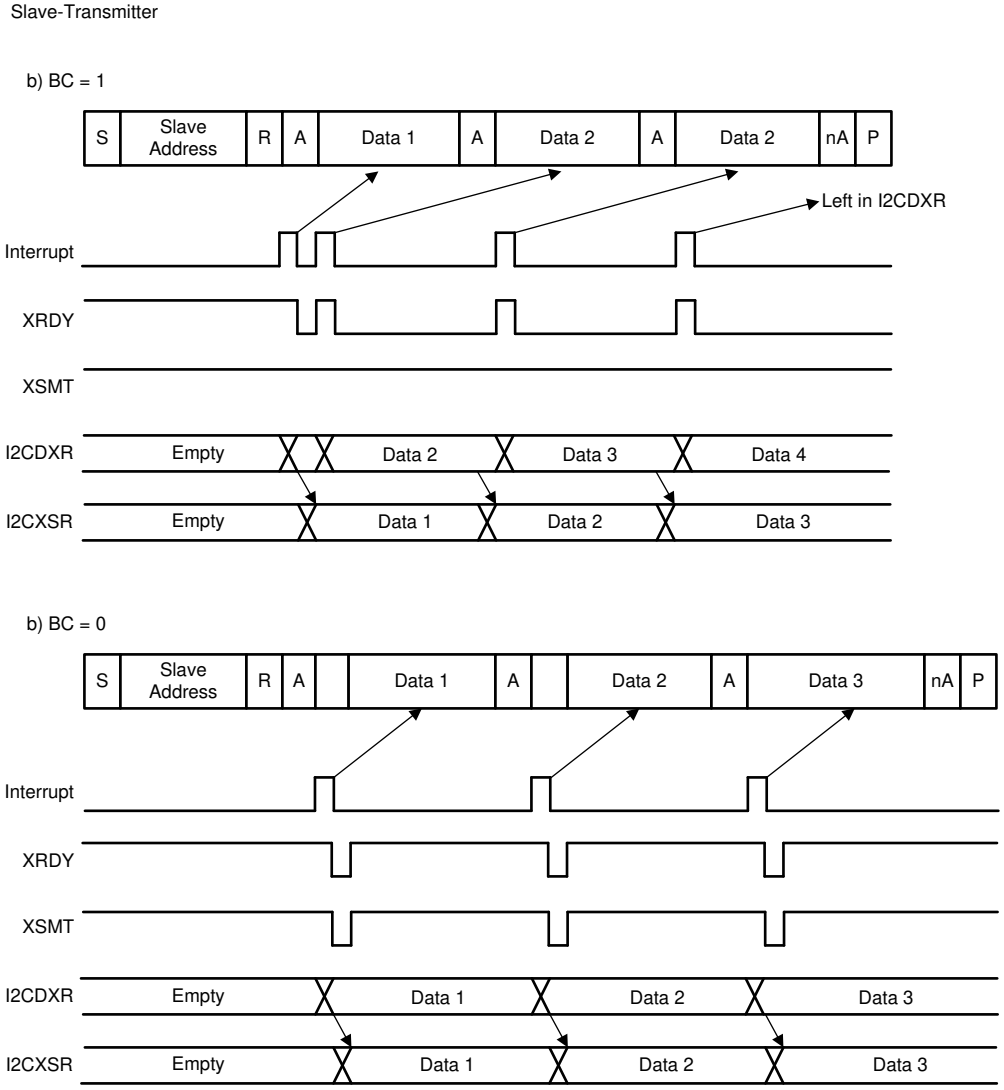
Figure 33-15. Enable Paths of the I2C Interrupt Requests



The normal transmit interrupt timing makes it possible for stale data to remain in the transmit buffer if a transaction is aborted in the middle of a byte. To avoid this, set the FCM bit in the I2CEMDR register. When this bit is set, the transmit data ready interrupt is generated only when data is required for a bus transaction. In master mode, the interrupt is first generated when the ACK of the address byte is received. In slave mode, the interrupt is first generated when the address is matched. Further interrupts are generated when the data is ACKed. In this mode XRDY is asserted at the same time as the transmit ready interrupt.

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in Figure 33-16 demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a slave-transmitter.

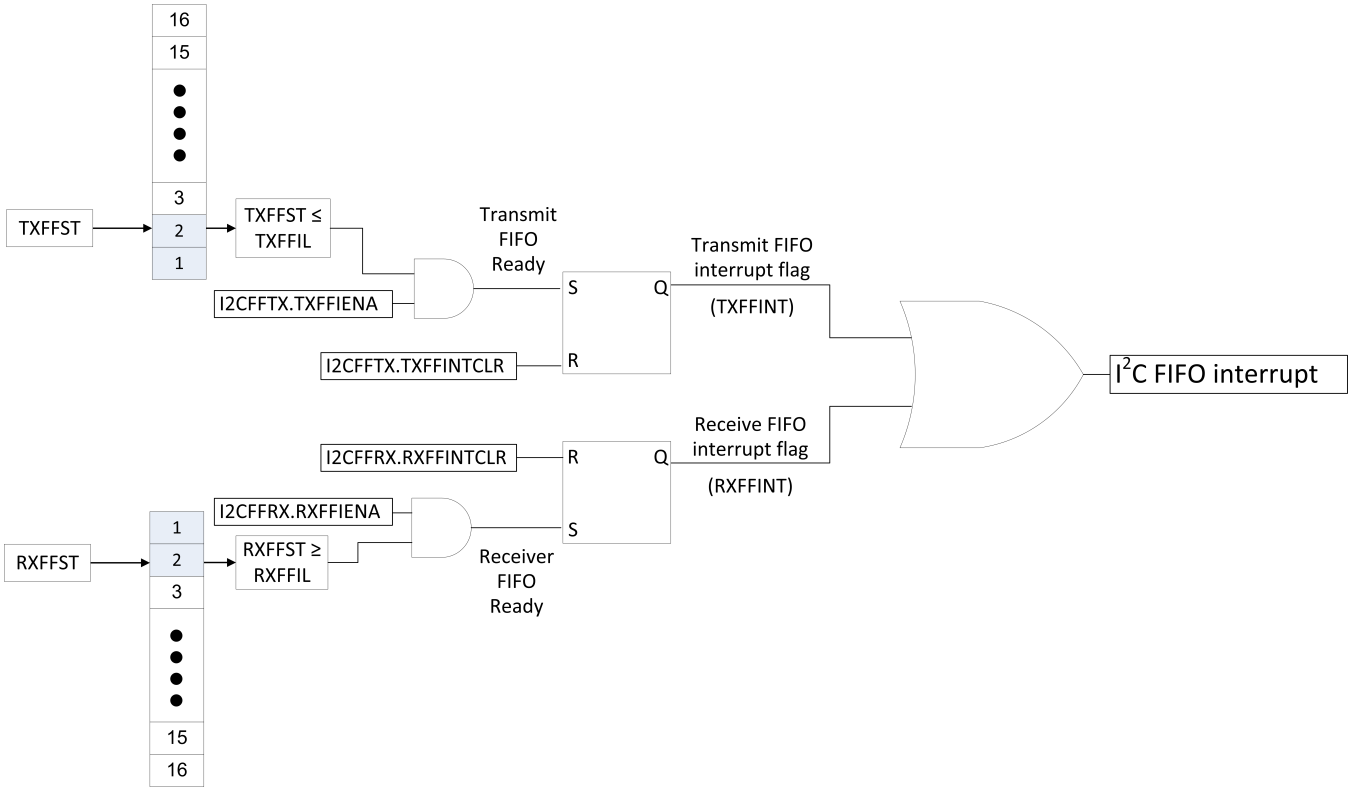
Figure 33-16. Backwards Compatibility Mode Bit, Slave Transmitter



33.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 33-17 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

Figure 33-17. I2C_FIFO_interrupt



33.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMDR). All status bits (in I2CSTR) are forced to their default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the $\overline{\text{XRS}}$ pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the $\overline{\text{XRS}}$ pin is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

33.6 I2C Registers

This section describes the C28x I2C Module Registers.

33.6.1 I2C Base Addresses

Table 33-7. I2C Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
I2caRegs	I2C_REGS	I2CA_BASE	0x0000_7300	YES	YES	-	-	YES
I2cbRegs	I2C_REGS	I2CB_BASE	0x0000_7340	YES	YES	-	-	YES

33.6.2 I2C_REGS Registers

Table 33-8 lists the I2C_REGS registers. All register offset addresses not listed in Table 33-8 should be considered as reserved locations and the register contents should not be modified.

Table 33-8. I2C_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	I2COAR	I2C Own address		Go
1h	I2CIER	I2C Interrupt Enable		Go
2h	I2CSTR	I2C Status		Go
3h	I2CCLKL	I2C Clock low-time divider		Go
4h	I2CCLKH	I2C Clock high-time divider		Go
5h	I2CCNT	I2C Data count		Go
6h	I2CDRR	I2C Data receive		Go
7h	I2CSAR	I2C Slave address		Go
8h	I2CDXR	I2C Data Transmit		Go
9h	I2CMDR	I2C Mode		Go
Ah	I2CISRC	I2C Interrupt Source		Go
Bh	I2CEMDR	I2C Extended Mode		Go
Ch	I2CPSC	I2C Prescaler		Go
20h	I2CFFTX	I2C FIFO Transmit		Go
21h	I2CFFRX	I2C FIFO Receive		Go

Complex bit access types are encoded to fit into small table cells. Table 33-9 shows the codes that are used for access types in this section.

Table 33-9. I2C_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

33.6.2.1 I2COAR Register (Offset = 0h) [reset = 0h]

I2COAR is shown in Figure 33-18 and described in Table 33-10.

Return to the Summary Table.

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used
write 0s to bits 9-7.

9-0	OAR	R/W	0h	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit slave address of the I2C module. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit slave address of the I2C module. Reset type: SYSRSn

33.6.2.2 I2CIER Register (Offset = 1h) [reset = 0h]

I2CIER is shown in Figure 33-19 and described in Table 33-11.

Return to the Summary Table.

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

33.6.2.3 I2CSTR Register (Offset = 2h) [reset = 410h]

I2CSTR is shown in Figure 33-20 and described in Table 33-12.

Return to the Summary Table.

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

Figure 33-20. I2CSTR Register

Table 33-12. I2CSTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	SDIR	R/W1C	0h	Slave direction bit Reset type: SYSRSn 0h (R/W) = I2C is not addressed as a slave transmitter. SDIR is cleared by one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - Digital loopback mode is enabled. - A START or STOP condition occurs on the I2C bus. 1h (R/W) = I2C is addressed as a slave transmitter.
13	NACKSNT	R/W1C	0h	NACK sent bit. This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Reset type: SYSRSn 0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset). 1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.
12	BB	R	0h	Bus busy bit. BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information Reset type: SYSRSn 0h (R/W) = Bus free. BB is cleared by any one of the following events: - The I2C module receives or transmits a STOP bit (bus free). - The I2C module is reset. 1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus.

Table 33-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	RSFULL	R	0h	Receive shift register full bit. RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read. Reset type: SYSRSn 0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events: - I2CDRR is read is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - The I2C module is reset. 1h (R/W) = Overrun detected
10	XSMT	R	1h	Transmit shift register empty bit. XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin. Reset type: SYSRSn 0h (R/W) = Underflow detected (empty) 1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events: - Data is written to I2CDXR. - The I2C module is reset
9	AAS	R	0h	Addressed-as-slave bit Reset type: SYSRSn 0h (R/W) = In the 7-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or by a slave address different from the I2C peripheral's own slave address. 1h (R/W) = The I2C module has recognized its own slave address or an address of all zeros (general call).
8	AD0	R	0h	Address 0 bits Reset type: SYSRSn 0h (R/W) = AD0 has been cleared by a START or STOP condition. 1h (R/W) = An address of all zeros (general call) is detected.
7	RESERVED	R	0h	Reserved
6	BYTESENT	R/W1C	0h	Byte Transmit over indication. BYTESENT is set when the master/slave has successfully sent the byte on SCL/SDA lines. This is diagnostic register which needs to be explicitly cleared by Software. In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions. Reset type: SYSRSn 0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The I2C module has completed the transmission of a byte.

Table 33-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SCD	R/W1C	0h	Stop condition detected bit. SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set. Reset type: SYSRSn 0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events: - I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit. - SCD is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = A STOP condition has been detected on the I2C bus.
4	XRDY	R	1h	Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data. FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). The CPU can poll XRDY or use the XRDY interrupt request When in FIFO mode, use TXFFINT instead. FCM=1: XRDY is asserted only when next data is required it gets de asserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode. Reset type: SYSRSn 0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR. 1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSR. XRDY is also forced to 1 when the I2C module is reset.
3	RRDY	R/W1C	0h	Receive-data-ready interrupt flag bit. When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request When in FIFO mode, use RXFFINT instead. Reset type: SYSRSn 0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - RRDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.

Table 33-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	ARDY	R/W1C	0h	Register-access-ready interrupt flag bit (only Applicable when the I2C module is in the master mode). ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request Reset type: SYSRSn 0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events: - The I2C module starts using the current register contents. - ARDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The registers are ready to be accessed. In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0). In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.
1	NACK	R/W1C	0h	No-acknowledgment interrupt flag bit. NACK applies when the I2C module is a transmitter (master or slave). NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK) from the receiver. The CPU can poll NACK or use the NACK interrupt request. Reset type: SYSRSn 0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events: - An acknowledge bit (ACK) has been sent by the receiver. - NACK is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received. Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment.

Table 33-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	ARBL	R/W1C	0h	Arbitration-lost interrupt flag bit (only applicable when the I2C module is a master-transmitter). ARBL primarily indicates when the I2C module has lost an arbitration contest with another mastertransmitter. The CPU can poll ARBL or use the ARBL interrupt request. Reset type: SYSRSn 0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events: - AL is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an AL interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = Arbitration lost. AL is set by any one of the following events: - The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously. - The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1. When AL becomes 1, the MST and STP bits of I2CMDR are cleared, and the I2C module becomes a slave-receiver.

33.6.2.4 I2CCLKL Register (Offset = 3h) [reset = 0h]

I2CCLKL is shown in Figure 33-21 and described in Table 33-13.

Return to the Summary Table.

To produce the high time duration of the master clock, the period of the module clock is multiplied by (ICCL + d). d is an adjustment factor based on the prescaler. See the Clock Divider Registers section of the Introduction for details. Note: These bits must be set to a non-zero value for proper I2C clock generation. Reset type: SYSRSn

33.6.2.6 I2CCNT Register (Offset = 5h) [reset = 0h]

I2CCNT is shown in Figure 33-23 and described in Table 33-15.

Return to the Summary Table.

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a master receiver. In the repeat mode (RM = 1), I2CCNT is not used.

The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the master mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

Bit	Field	Type	Reset	Description
15-0	I2CCNT	R/W	0h	Data count value. I2CCNT indicates the number of data bytes to transfer or receive. The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1. The start value loaded to the internal data counter is 65536. The start value loaded to internal data counter is 1-65535. Reset type: SYSRSn

33.6.2.7 I2CDRR Register (Offset = 6h) [reset = 0h]

I2CDRR is shown in Figure 33-24 and described in Table 33-16.

Return to the Summary Table.

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.

If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.

When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

33.6.2.8 I2CSAR Register (Offset = 7h) [reset = 3FFh]

I2CSAR is shown in Figure 33-25 and described in Table 33-17.

Return to the Summary Table.

The I2C slave address register (I2CSAR) is a 16-bit register for storing the next slave address that will be transmitted by the I2C module when it is a master. The SAR field of I2CSAR contains a 7-bit or 10-bit slave address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a slave, or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used
write 0s to bits 9-7.

Figure 33-25. I2CSAR Register

15	14	13	12	11	10	9	8

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	SAR	R/W	3FFh	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit slave address that the I2C module transmits when it is in the master-transmitter mode. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit slave address that the I2C module transmits when it is in the master transmitter mode. Reset type: SYSRSn

33.6.2.9 I2CDXR Register (Offset = 8h) [reset = 0h]

I2CDXR is shown in Figure 33-26 and described in Table 33-18.

Return to the Summary Table.

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMDR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR.

After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.

When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

33.6.2.10 I2CMDR Register (Offset = 9h) [reset = 0h]

I2CMDR is shown in Figure 33-27 and described in Table 33-19.

Return to the Summary Table.

The I2C mode register (I2CMDR) is a 16-bit register that contains the control bits of the I2C module.

Figure 33-27. I2CMDR Register

15	14	13	12	11	10	9	8

R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h		

Table 33-19. I2CMDR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	NACKMOD	R/W	0h	NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver. Reset type: SYSRSn 0h (R/W) = In the slave-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit. In the master-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit 1h (R/W) = In either slave-receiver or master-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared. Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.
14	FREE	R/W	0h	This bit controls the action taken by the I2C module when a debugger breakpoint is encountered. Reset type: SYSRSn 0h (R/W) = When I2C module is master: If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops. When I2C module is slave: A breakpoint forces the I2C module to stop when the current transmission/reception is complete. 1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.
13	STT	R/W	0h	START condition bit (only applicable when the I2C module is a master). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0. Reset type: SYSRSn 0h (R/W) = In the master mode, STT is automatically cleared after the START condition has been generated. 1h (R/W) = In the master mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus
12	RESERVED	R	0h	Reserved

Table 33-19. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	STOP condition bit (only applicable when the I2C module is a master). In the master mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions. Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message. Reset type: SYSRSn 0h (R/W) = STP is automatically cleared after the STOP condition has been generated 1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.
10	MST	R/W	0h	Master mode bit. MST determines whether the I2C module is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I2C master generates a STOP condition Reset type: SYSRSn 0h (R/W) = Slave mode. The I2C module is a slave and receives the serial clock from the master. 1h (R/W) = Master mode. The I2C module is a master and generates the serial clock on the SCL pin.
9	TRX	R/W	0h	Transmitter mode bit. When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode. Reset type: SYSRSn 0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin. 1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.
8	XA	R/W	0h	Expanded address enable bit. Reset type: SYSRSn 0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit slave addresses (from bits 6-0 of I2CSAR), and its own slave address has 7 bits (bits 6-0 of I2COAR). 1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit slave addresses (from bits 9-0 of I2CSAR), and its own slave address has 10 bits (bits 9-0 of I2COAR).
7	RM	R/W	0h	Repeat mode bit (only applicable when the I2C module is a master-transmitter). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions Reset type: SYSRSn 0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module. 1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.

Table 33-19. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	DLB	R/W	0h	Digital loopback mode bit. Reset type: SYSRSn 0h (R/W) = Digital loopback mode is disabled. 1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the MST bit must be 1. In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: n = ((I2C input clock frequency/module clock frequency) x 8) The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR. Note: The free data format (FDF = 1) is not supported in the digital loopback mode.
5	IRS	R/W	0h	I2C module reset bit. Reset type: SYSRSn 0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values. 1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.
4	STB	R/W	0h	START byte mode bit. This bit is only applicable when the I2C module is a master. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C module is a slave, it ignores a START byte from a master, regardless of the value of the STB bit. Reset type: SYSRSn 0h (R/W) = The I2C module is not in the START byte mode. 1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates: 1. A START condition 2. A START byte (0000 0001b) 3. A dummy acknowledge clock pulse 4. A repeated START condition Then, as normal, the I2C module sends the slave address that is in I2CSAR.
3	FDF	R/W	0h	Free data format mode bit. Reset type: SYSRSn 0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit. 1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5. The free data format is not supported in the digital loopback mode (DLB=1).

Table 33-19. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	BC	R/W	0h	Bit count bits. BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits. Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified Reset type: SYSRSn 0h (R/W) = 8 bits per data byte 1h (R/W) = 1 bit per data byte 2h (R/W) = 2 bits per data byte 3h (R/W) = 3 bits per data byte 4h (R/W) = 4 bits per data byte 5h (R/W) = 5 bits per data byte 6h (R/W) = 6 bits per data byte 7h (R/W) = 7 bits per data byte

33.6.2.11 I2CISRC Register (Offset = Ah) [reset = 0h]

I2CISRC is shown in Figure 33-28 and described in Table 33-20.

Return to the Summary Table.

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

Figure 33-28. I2CISRC Register

15	14	13	12	11	10	9	8

R-0h					R-0h		

Table 33-20. I2CISRC Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11-8	WRITE_ZEROS	R/W	0h	TI internal testing bits These reserved bit locations should always be written as zeros. Reset type: SYSRSn
7-3	RESERVED	R	0h	Reserved
2-0	INTCODE	R	0h	Interrupt code bits. The binary code in INTCODE indicates the event that generated an I2C interrupt. A CPU read will clear this field. If another lower priority interrupt is pending and enabled, the value corresponding to that interrupt will then be loaded. Otherwise, the value will stay cleared. In the case of an arbitration lost, a no-acknowledgment condition detected, or a stop condition detected, a CPU read will also clear the associated interrupt flag bit in the I2CSTR register. Emulator reads will not affect the state of this field or of the status bits in the I2CSTR register. Reset type: SYSRSn 0h (R/W) = None 1h (R/W) = Arbitration lost 2h (R/W) = No-acknowledgment condition detected 3h (R/W) = Registers ready to be accessed 4h (R/W) = Receive data ready 5h (R/W) = Transmit data ready 6h (R/W) = Stop condition detected 7h (R/W) = Addressed as slave

33.6.2.12 I2CEMDR Register (Offset = Bh) [reset = 1h]

I2CEMDR is shown in Figure 33-29 and described in Table 33-21.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	FCM	R/W	0h	Forward Compatibility mode. This bit when programmed brings the functionality of Tx request only when Tx data required regardless of data status in Tx buffer for non-FIFO mode. This register affects the XRDY behavior hence needs to be set after releasing the IRS (I2CMDR[5]). Reset type: SYSRSn 0h (R/W) = Legacy functionality of requesting Tx data upon buffer copy to shift register or upon start condition is active. Stale data is reused after illegal start, ARB Lost, NACK conditions. 1h (R/W) = New functionality of requesting data only upon ACK (address/data) is active.
0	BC	R/W	1h	Backwards compatibility mode. This bit affects the timing of the transmit status bits (XRDY and XSMT) in the I2CSTR register when in slave transmitter mode. Reset type: SYSRSn 0h (R/W) = See the "Backwards Compatibility Mode Bit, Slave Transmitter" Figure for details. 1h (R/W) = See the "Backwards Compatibility Mode Bit, Slave Transmitter" Figure for details.

33.6.2.13 I2CPSC Register (Offset = Ch) [reset = 0h]

I2CPSC is shown in Figure 33-30 and described in Table 33-22.

Return to the Summary Table.

The I2C prescaler register (I2CPSC) is a 16-bit register (see Figure 14-21) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.

IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

Figure 33-30. I2CPSC Register

15-8	RESERVED	R	0h	Reserved
7-0	IPSC	R/W	0h	I2C prescaler divide-down value. IPSC determines how much the CPU clock is divided to create the module clock of the I2C module: module clock frequency = I2C input clock frequency/(IPSC + 1) Note: IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). Reset type: SYSRSn

33.6.2.14 I2CFFTX Register (Offset = 20h) [reset = 0h]

I2CFFTX is shown in Figure 33-31 and described in Table 33-23.

Return to the Summary Table.

The I2C transmit FIFO register (I2CFFTX) is a 16-bit register that contains the I2C FIFO mode enable bit as well as the control and status bits for the transmit FIFO mode of operation on the I2C peripheral.

Figure 33-31. I2CFFTX Register

15	14	13	12	11	10	9	8
RESERVED	I2CFFEN	TXFFRST	TXFFST				
R-0h	R/W-0h	R/W-0h	R-0h

R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 33-23. I2CFFTX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	I2CFFEN	R/W	0h	I2C FIFO mode enable bit. This bit must be enabled for either the transmit or the receive FIFO to operate correctly. Reset type: SYSRSn 0h (R/W) = Disable the I2C FIFO mode. 1h (R/W) = Enable the I2C FIFO mode.
13	TXFFRST	R/W	0h	Transmit FIFO Reset Reset type: SYSRSn 0h (R/W) = Reset the transmit FIFO pointer to 0000 and hold the transmit FIFO in the reset state. 1h (R/W) = Enable the transmit FIFO operation.
12-8	TXFFST	R	0h	Contains the status of the transmit FIFO: xxxxx Transmit FIFO contains xxxxx bytes. 00000 Transmit FIFO is empty. Note: Since these bits are reset to zero, the transmit FIFO interrupt flag will be set when the transmit FIFO operation is enabled and the I2C is taken out of reset. This will generate a transmit FIFO interrupt if enabled. To avoid any detrimental effects from this, write a one to the TXFFINTCLR once the transmit FIFO operation is enabled and the I2C is taken out of reset. Reset type: SYSRSn
7	TXFFINT	R	0h	Transmit FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the TXFFINTCLR bit. If the TXFFIENA bit is set, this bit will generate an interrupt when it is set. Reset type: SYSRSn 0h (R/W) = Transmit FIFO interrupt condition has not occurred. 1h (R/W) = Transmit FIFO interrupt condition has occurred.
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO Interrupt Flag Clear Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a 0. 1h (R/W) = Writing a 1 to this bit clears the TXFFINT flag.
5	TXFFIENA	R/W	0h	Transmit FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = Disabled. TXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. TXFFINT flag does generate an interrupt when set.

Table 33-23. I2CFFTX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	Transmit FIFO interrupt level. These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

33.6.2.15 I2CFFRX Register (Offset = 21h) [reset = 0h]

I2CFFRX is shown in Figure 33-32 and described in Table 33-24.

Return to the Summary Table.

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

Figure 33-32. I2CFFRX Register

15	14	13	12	11	10	9	8
RESERVED		RXFFRST	RXFFST				
R-0h		R/W-0h	R-0h				
7	6	5	4	3	2	1	0
RXFFINT	RXFFINTCLR	RXFFIENA	RXFFIL				
R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 33-24. I2CFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	RXFFRST	R/W	0h	I2C receive FIFO reset bit Reset type: SYSRSn 0h (R/W) = Reset the receive FIFO pointer to 0000 and hold the receive FIFO in the reset state. 1h (R/W) = Enable the receive FIFO operation.
12-8	RXFFST	R	0h	Contains the status of the receive FIFO: xxxxx Receive FIFO contains xxxxx bytes 00000 Receive FIFO is empty. Reset type: SYSRSn
7	RXFFINT	R	0h	Receive FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the RXFFINTCLR bit. If the RXFFIENA bit is set, this bit will generate an interrupt when it is set Reset type: SYSRSn 0h (R/W) = Receive FIFO interrupt condition has not occurred. 1h (R/W) = Receive FIFO interrupt condition has occurred.
6	RXFFINTCLR	R-0/W1S	0h	Receive FIFO interrupt flag clear bit. Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a zero. 1h (R/W) = Writing a 1 to this bit clears the RXFFINT flag.
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable bit. Reset type: SYSRSn 0h (R/W) = Disabled. RXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. RXFFINT flag does generate an interrupt when set.
4-0	RXFFIL	R/W	0h	Receive FIFO interrupt level. These bits set the status level that will set the receive interrupt flag. When the RXFFST4-0 bits reach a value equal to or greater than these bits, the RXFFINT flag is set. This will generate an interrupt if the RXFFIENA bit is set. Note: Since these bits are reset to zero, the receive FIFO interrupt flag will be set if the receive FIFO operation is enabled and the I2C is taken out of reset. This will generate a receive FIFO interrupt if enabled. To avoid this, modify these bits on the same instruction as or prior to setting the RXFFRST bit. Because the I2C on this device has a 16-level receive FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

Multichannel Buffered Serial Port (McBSP)

This document describes the multichannel buffered serial port (McBSP) of this device.

Topic **Page**

34.1 Overview

This device provides up to two high-speed multichannel buffered serial ports (McBSPs) that allow direct interface to codecs and other devices in a system. The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 34-1.

Data is communicated to devices interfaced with the McBSP via the data transmit (DX) pin for transmission and via the data receive (DR) pin for reception. Control information in the form of clocking and frame synchronization is communicated via the following pins: CLKX (transmit clock), CLKR (receive clock), FSX (transmit frame synchronization), and FSR (receive frame synchronization).

The CPU and the DMA controller communicate with the McBSP through 16-bit wide registers accessible via the internal peripheral bus. The CPU or the DMA controller writes the data to be transmitted to the data transmit registers (DXR1, DXR2). Data written to the DXRs is shifted out to the DX pin via the transmit shift registers (XSR1, XSR2). Similarly, receive data on the DR pin is shifted into the receive shift registers (RSR1, RSR2) and copied into the receive buffer registers (RBR1, RBR2). The contents of the receive buffer registers (RBRs) is then copied to the data receive registers (DRRs), which can be read by the CPU or the DMA controller. This allows simultaneous movement of internal and external data communications.

If the serial word length is 8 bits, 12 bits, or 16 bits, the DRR2, RBR2, RSR2, DXR2, and XSR2 registers are not used (written, read, or shifted) For larger word lengths, these registers are needed to hold the most significant bits.

The frame and clock loop-back is implemented at chip level to enable CLKX and FSX to drive CLKR and FSR. If the loop-back is enabled, the CLKR and FSR get their signals from the CLKX and FSX pads; instead of the CLKR and FSR pins.

34.1.1 Features of the McBSPs

The McBSPs feature:

- Full-duplex communication
- Double-buffered transmission and triple-buffered reception, allowing a continuous data stream
- Independent clocking and framing for reception and transmission
- The capability to send interrupts to the CPU and to send DMA events to the DMA controller
- 128 channels for transmission and reception
- Multichannel selection modes that enable or disable block transfers in each of the channels
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices
- Support for external generation of clock signals and frame-synchronization signals
- A programmable sample rate generator for internal generation and control of clock signals and frame-synchronization signals
- Programmable polarity for frame-synchronization pulses and clock signals
- Direct interface to:
  - T1/E1 framers
  - IOM-2 compliant devices
  - AC97-compliant devices (the necessary multiphase frame capability is provided)
  - I2S compliant devices
  - SPI devices
- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits

NOTE: A value of the chosen data size is referred to as a *serial word* or *word* throughout the McBSP documentation. Elsewhere, *word* is used to describe a 16-bit value.

- μ-law and A-law companding
- The option of transmitting/receiving 8-bit data with the LSB first

- Status bits for flagging exception/error conditions
- ABIS mode is not supported

34.1.2 McBSP Pins/Signals

Table 34-1 describes the McBSP interface pins and some internal signals.

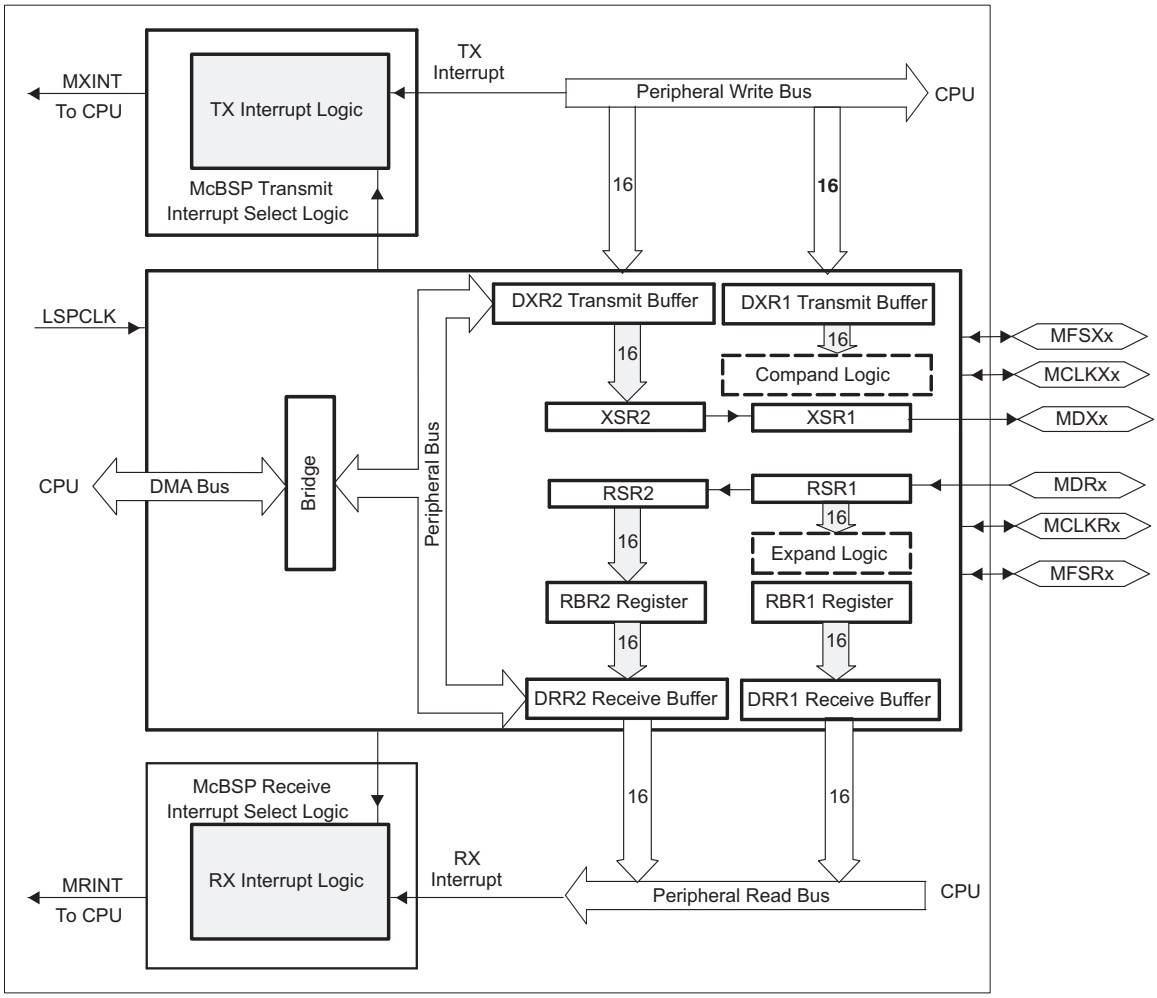
Table 34-1. McBSP Interface Pins/Signals

McBSP-A Pin	McBSP-B Pin	Type	Description
MCLKRA	MCLKRB	I/O	Supplies or reflects the receive clock; supplys the input clock of the sample rate generator
MCLKXA	MCLKXB	I/O	Supplys or reflects the transmit clock; supplys the input clock of the sample rate generator
MDRA	MDRB	I	Serial data receive pin
MDXA	MDXB	O	Serial data transmit pin
MFSRA	MFSRB	I/O	Supplys or reflects the receive frame-sync signal; controlsg sample rate generator synchronization when GSYNC = 1 (see Section 34.4.3)
MFSXA	MFSXB	I/O	Supplys or reflects the transmit frame-sync signal
CPU Interrupt Signals			
MRINT			Receive interrupt to CPU
MXINT			Transmit interrupt to CPU
DMA Events			
REVT			Receive synchronization event to DMA
XEVT			Transmit synchronization event to DMA

34.1.2.1 McBSP Generic Block Diagram

The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 34-1. The figure and the text in this section use generic pin names.

Figure 34-1. Conceptual Block Diagram of the McBSP



A Not available in all devices. See the device-specific data sheet

34.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

34.3 McBSP Operation

This section addresses the following topics:

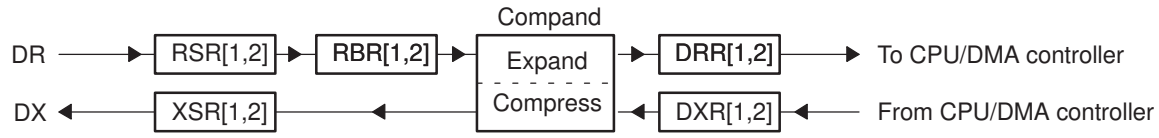
- Data transfer process
- Companding (compressing and expanding) data
- Clocking and framing data

- Frame phases
- McBSP reception
- McBSP transmission
- Interrupts and DMA events generated by McBSPs

34.3.1 Data Transfer Process of McBSPs

Figure 34-2 shows a diagram of the McBSP data transfer paths. The McBSP receive operation is triple-buffered, and transmit operation is double-buffered. The use of registers varies, depending on whether the defined length of each serial word is 16 bits.

Figure 34-2. McBSP Data Transfer Paths



34.3.1.1 Data Transfer Process for Word Length of 8, 12, or 16 Bits

If the word length is 16 bits or smaller, only one 16-bit register is needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are not used (written, read, or shifted).

Receive data arrives on the DR pin and is shifted into receive shift register 1 (RSR1). Once a full word is received, the content of RSR1 is copied to the receive buffer register 1 (RBR1), that is, if RBR1 is not full with previous data. RBR1 is then copied to the data receive register 1 (DRR1), unless the previous content of DRR1 has not been read by the CPU or the DMA controller. If the companding feature of the McBSP is implemented, the required word length is 8 bits and receive data is expanded into the appropriate format before being passed from RBR1 to DRR1. For more details about reception, see Section 34.3.5.

Transmit data is written by the CPU or the DMA controller to the data transmit register 1 (DXR1). If there is no previous data in the transmit shift register (XSR1), the value in DXR1 is copied to XSR1; otherwise, DXR1 is copied to XSR1 when the last bit of the previous data is shifted out on the DX pin. If selected, the companding module compresses 16-bit data into the appropriate 8-bit format before passing it to XSR1. After transmit frame synchronization, the transmitter begins shifting bits from XSR1 to the DX pin. For more details about transmission, see Section 34.3.6.

34.3.1.2 Data Transfer Process for Word Length of 20, 24, or 32 Bits

If the word length is larger than 16 bits, two 16-bit registers are needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are needed to hold the most significant bits.

Receive data arrives on the DR pin and is shifted first into RSR2 and then into RSR1. Once the full word is received, the contents of RSR2 and RSR1 are copied to RBR2 and RBR1, respectively, if RBR1 is not full. Then the contents of RBR2 and RBR1 are copied to DRR2 and DRR1, respectively, unless the previous content of DRR1 has not been read by the CPU or the DMA controller. The CPU or the DMA controller must read data from DRR2 first and then from DRR1. When DRR1 is read, the next RBR-to-DRR copy occurs. For more details about reception, see Section 34.3.5.

For transmission, the CPU or the DMA controller must write data to DXR2 first and then to DXR1. When new data arrives in DXR1, if there is no previous data in XSR1, the contents of DXR2 and DXR1 are copied to XSR2 and XSR1, respectively; otherwise, the contents of the DXRs are copied to the XSRs when the last bit of the previous data is shifted out on the DX pin. After transmit frame synchronization, the transmitter begins shifting bits from the XSRs to the DX pin. For more details about transmission, see Section 34.3.6.

34.3.2 Companding (Compressing and Expanding) Data

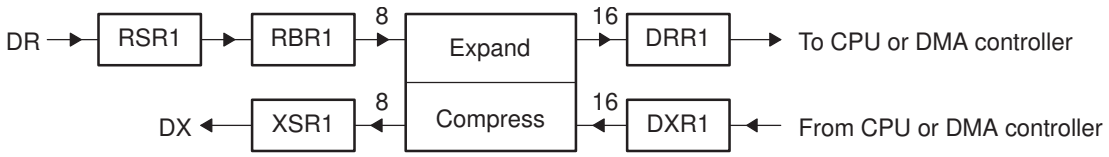
Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 34-3 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to twos complement format.

Figure 34-3. Companding Processes

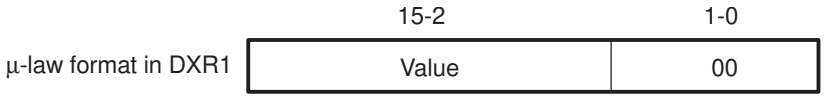


34.3.2.1 Companding Formats

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The receive sign-extension and justification mode specified in RJUST is ignored when companding is used.

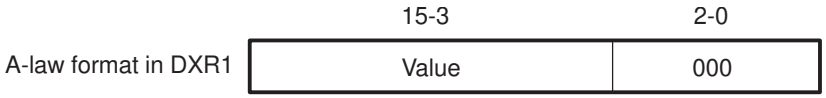
For transmission using μ-law compression, the 14 data bits must be left-justified in DXR1 with the remaining two low-order bits filled with 0s as shown in Figure 34-4.

Figure 34-4. μ-Law Transmit Data Companding Format



For transmission using A-law compression, the 13 data bits must be left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 34-5.

Figure 34-5. A-Law Transmit Data Companding Format



34.3.2.2 Capability to Compand Internal Data

If the McBSP is unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. This can be used to:

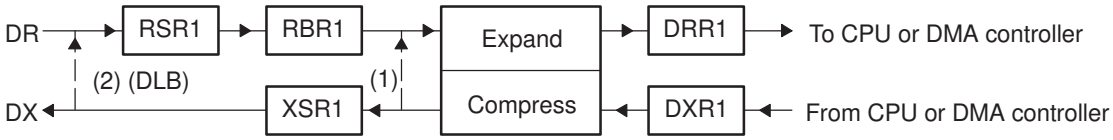
- Convert linear to the appropriate μ-law or A-law format
- Convert μ-law or A-law to the linear format
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 34-6 shows two methods by which the McBSP can compand internal data. Data paths for these two methods are used to indicate:

- When both the transmit and receive sections of the serial port are reset, DRR1 and DXR1 are connected internally through the companding logic. Values from DXR1 are compressed, as selected by XCOMPAND, and then expanded, as selected by RCOMPAND. RRDY and XRDY bits are not set. However, data is available in DRR1 within four CPU clocks after being written to DXR1.

  The advantage of this method is its speed. The disadvantage is that there is no synchronization available to the CPU and DMA to control the flow. DRR1 and DXR1 are internally connected if the (X/R)COMPAND bits are set to 10b or 11b (compand using μ-law or A-law).
- The McBSP is enabled in digital loopback mode with companding appropriately enabled by RCOMPAND and XCOMPAND. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or synchronization events (REVT and XEVT) allow synchronization of the CPU or DMA to these conversions, respectively. Here, the time for this companding depends on the serial bit rate selected.

Figure 34-6. Two Methods by Which the McBSP Can Compand Internal Data



34.3.2.3 Reversing Bit Order: Option to Transfer LSB First

Generally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits, and LSB-first ordering is done.

34.3.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

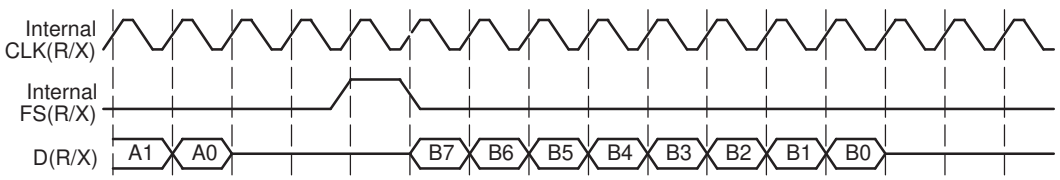
34.3.3.1 Clocking

Data is shifted one bit at a time from the DR pin to the RSR(s) or from the XSR(s) to the DX pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR) controls bit transfers from the DR pin to the RSR(s). The transmit clock signal (CLKX) controls bit transfers from the XSR(s) to the DX pin. CLKR or CLKX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP. The polarities of CLKR and CLKX are programmable.

Figure 34-7 shows how the clock signal controls the timing of each bit transfer on the pin.

Figure 34-7. Example - Clock Signal Control of Bit Transfer Timing



NOTE: The McBSP cannot operate at a frequency faster than ½ the LSPCLK frequency. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX and/or CLKR, choose an appropriate input clock frequency and divide down value (CLKDV) (that is, be certain that CLKX or CLKR ≤ LSPCLK/2).

34.3.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (DR or DX) are transferred in a group called a serial word. You can define how many bits are in a word.

Bits coming in on the DR pin are held in RSR until RSR holds a full serial word. Only then is the word passed to RBR (and ultimately to the DRR).

During transmission, XSR does not accept new data from DXR until a full serial word has been passed from XSR to the DX pin.

In the exmaple in Figure 34-7, an 8-bit word size was defined (see bits 7 through 0 of word B being transferred).

34.3.3.3 Frames and Frame Synchronization

One or more words are transferred in a group called a frame. You can define how many words are in a frame.

All of the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR) signal initiate frame transfers on the DR data pin. Pulses on the transmit frame-sync (FSX) signal initiate frame transfers on DX. FSR or FSX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP.

In Figure 34-7, a one-word frame is transferred when a frame-synchronization pulse occurs.

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

34.3.3.4 Generating Transmit and Receive Interrupts

The McBSP can send receive and transmit interrupts to the CPU to indicate specific events in the McBSP. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses. Set the appropriate interrupt mode bits to 10b (for reception, RINTM = 10b; for transmission, XINTM = 10b).

34.3.3.4.1 Detecting Frame-Synchronization Pulses, Even in Reset State

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating RINT when the receiver is in reset). In this case, FSRM/FSXM and FSRP/FSXP still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the CPU clock and then sent to the CPU in the form of RINT and XINT at the point at which they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and after this occurs the CPU can take the serial port out of reset safely.

34.3.3.5 Ignoring Frame-Synchronization Pulses

The McBSP can be configured to ignore transmit and/or receive frame-synchronization pulses. To have the receiver or transmitter recognize frame-synchronization pulses, clear the appropriate frame-synchronization ignore bit (RFIG = 0 for the receiver, XFIG = 0 for the transmitter). To have the receiver or transmitter ignore frame-synchronization pulses until the desired frame length or number of words is reached, set the appropriate frame-synchronization ignore bit (RFIG = 1 for the receiver, XFIG = 1 for the transmitter). For more details on unexpected frame-synchronization pulses, see one of the following topics:

- *Unexpected Receive Frame-Synchronization Pulse* (see Section 34.5.3)
- *Unexpected Transmit Frame-Synchronization Pulse* (see Section 34.5.6)

You can also use the frame-synchronization ignore function for data packing (for more details, see Section 34.11.2).

34.3.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown by Example 1.

Example 1: McBSP Frame Frequency

$$\text{Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Clock Cycles Between Frame- Sync Pulses}}$$

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

34.3.3.7 Maximum Frame Frequency

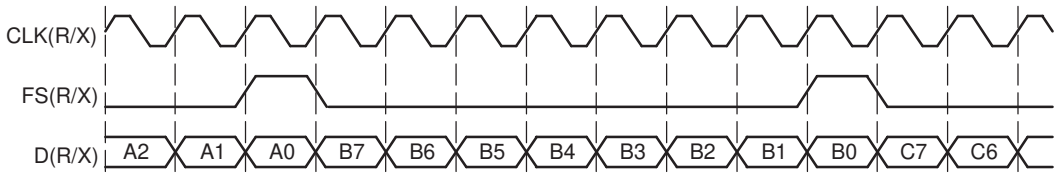
The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown by Example 2.

Example 2: McBSP Maximum Frame Frequency

$$\text{Maximum Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Bits Per Frame}}$$

Figure 34-8 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 34-8. McBSP Operating at Maximum Packet Frequency



If there is a 1-bit data delay as shown in this figure, the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, making frame-synchronization pulses redundant. Theoretically, only an initial frame-synchronization pulse is required to initiate a multipacket transfer.

The McBSP supports operation of the serial port in this fashion by ignoring the successive frame-synchronization pulses. Data is clocked into the receiver or clocked out of the transmitter during every clock cycle.

NOTE: For XDATDLY = 0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX). For more details, see Section 34.9.13.

34.3.4 Frame Phases

The McBSP allows you to configure each frame to contain one or two phases. The number of words and the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, you might define a frame as consisting of one phase containing two words of 16 bits each, followed by a second phase consisting of 10 words of 8 bits each. This configuration permits you to compose frames for custom applications or, in general, to maximize the efficiency of data transfers.

34.3.4.1 Number of Phases, Words, and Bits Per Frame

Table 34-2 shows which bit-fields in the receive control registers (RCR1 and RCR2) and in the transmit control registers (XCR1 and XCR2) determine the number of phases per frame, the number of words per frame, and number of bits per word for each phase, for the receiver and transmitter. The maximum number of words per frame is 128 for a single-phase frame and 256 for a dual-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

Table 34-2. Register Bits That Determine the Number of Phases, Words, and Bits

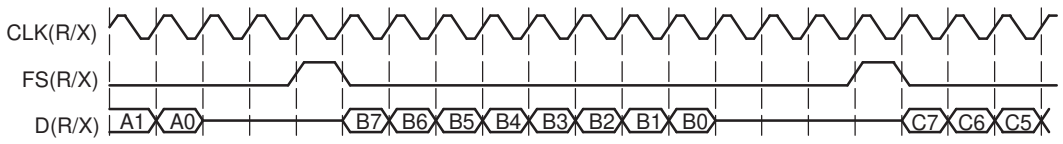
Operation	Number of Phases	Words per Frame Set With	Bits per Word Set With
Reception	1 (RPHASE = 0)	RFRLEN1	RWDLEN1
Reception	2 (RPHASE = 1)	RFRLEN1 and RFRLEN2	RWDLEN1 for phase 1
			RWDLEN2 for phase 2
Transmission	1 (XPHASE = 0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE = 1)	XFRLEN1 and XFRLEN2	XWDLEN1 for phase 1
			XWDLEN2 for phase 2

34.3.4.2 Single-Phase Frame Example

Figure 34-9 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the DX and DR pins are available one clock cycle after FS(R/X) goes active. The figure makes the following assumptions:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0b: 1 word per frame
- (R/X)WDLEN1 = 000b: 8-bit word length
- (R/X)FRLEN2 and (R/X)WDLEN2 are ignored
- CLK(X/R)P = 0: Receive data clocked on falling edge; transmit data clocked on rising edge
- FS(R/X)P = 0: Active-high frame-synchronization signals
- (R/X)DATDLY = 01b: 1-bit data delay

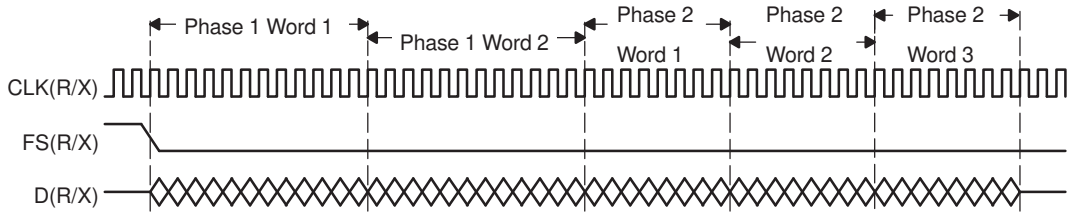
Figure 34-9. Single-Phase Frame for a McBSP Data Transfer



34.3.4.3 Dual-Phase Frame Example

Figure 34-10 shows an example of a frame where the first phase consists of two words of 12 bits each, followed by a second phase of three words of 8 bits each. The entire bit stream in the frame is contiguous. There are no gaps either between words or between phases.

Figure 34-10. Dual-Phase Frame for a McBSP Data Transfer

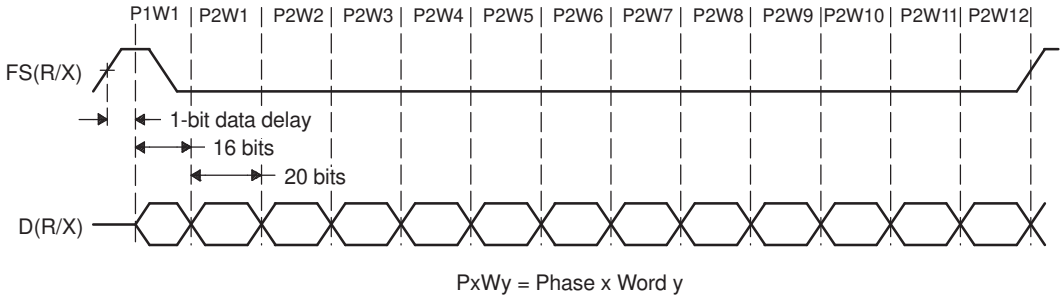


A XRDY gets asserted once per phase. So, if there are 2 phases, XRDY gets asserted twice (once per phase).

34.3.4.4 Implementing the AC97 Standard With a Dual-Phase Frame

Figure 34-11 shows an example of the Audio Codec '97 (AC97) standard, which uses the dual-phase frame feature. Notice that words, not individual bits, are shown on the D(R/X) signal. The first phase (P1) consists of a single 16-bit word. The second phase (P2) consists of twelve 20-bit words. The phase configurations are listed after the figure.

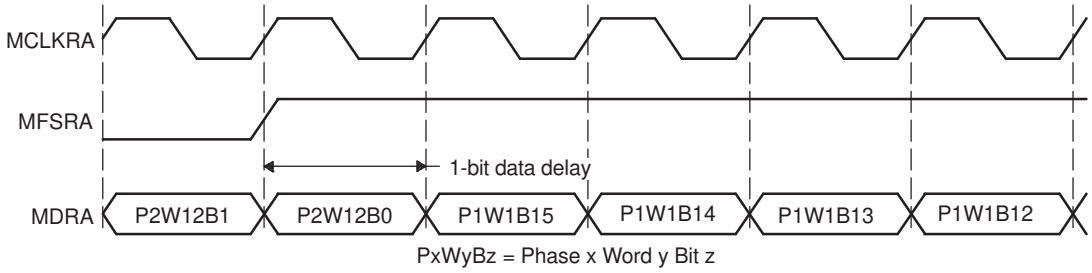
Figure 34-11. Implementing the AC97 Standard With a Dual-Phase Frame



- (R/X)PHASE = 1: Dual-phase frame
- (R/X)FRLEN1 = 0000000b: 1 word in phase 1
- (R/X)WDLEN1 = 010b: 16 bits per word in phase 1
- (R/X)FRLEN2 = 0001011b: 12 words in phase 2
- (R/X)WDLEN2 = 011b: 20 bits per word in phase 2
- CLKRP/CLKXP= 0: Receive data sampled on falling edge of internal CLKR / transmit data clocked on rising edge of internal CLKX
- FSRP/FSXP = 0: Active-high frame-sync signal
- (R/X)DATDLY = 01b: Data delay of 1 clock cycle (1-bit data delay)

Figure 34-12 shows the timing of an AC97-standard data transfer near frame synchronization. In this figure, individual bits are shown on D(R/X). Specifically, it shows the last two bits of phase 2 of one frame and the first four bits of phase 1 of the next frame. Regardless of the data delay, data transfers can occur without gaps. The first bit of the second frame (P1W1B15) immediately follows the last bit of the first frame (P2W12B0). Because a 1-bit data delay has been chosen, the transition on the frame-sync signal can occur when P2W12B0 is transferred.

Figure 34-12. Timing of an AC97-Standard Data Transfer Near Frame Synchronization

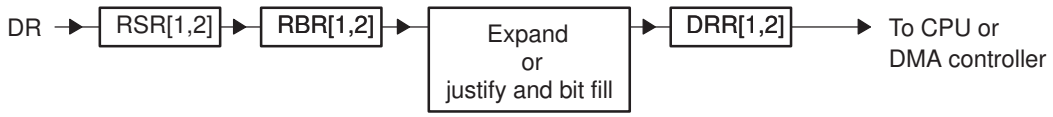


34.3.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP. For details about how to program the McBSP receiver, see Section 34.8.

Figure 34-13 and Figure 34-14 show how reception occurs in the McBSP. Figure 34-13 shows the physical path for the data. Figure 34-14 is a timing diagram showing signal activity for one possible reception scenario. A description of the process follows the figures.

Figure 34-13. McBSP Reception Physical Data Path

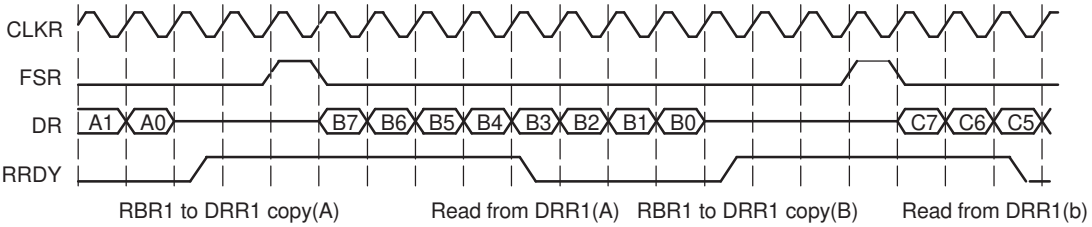


A RSR[1,2]: Receive shift registers 1 and 2

B RBR[1,2]: Receive buffer registers 1 and 2

C DRR[1,2]: Data receive registers 1 and 2

Figure 34-14. McBSP Reception Signal Activity



A CLKR: Internal receive clock

B FSR: Internal receive frame-synchronization signal

C DR: Data on DR pin

D RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the DR pin to the CPU or to the DMA controller:

1. The McBSP waits for a receive frame-synchronization pulse on internal FSR.
2. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the RDATDLY bits of RCR2.

   In the preceding timing diagram, a 1-bit data delay is selected.
3. The McBSP accepts data bits on the DR pin and shifts them into the receive shift register(s).

   If the word length is 16 bits or smaller, only RSR1 is used. If the word length is larger than 16 bits, RSR2 and RSR1 are used and RSR2 contains the most significant bits. For details on choosing a word length, see Section 34.8.8, *Set the Receive Word Length(s)*.
4. When a full word is received, the McBSP copies the contents of the receive shift register(s) to the receive buffer register(s), provided that RBR1 is not full with previous data.

   If the word length is 16 bits or smaller, only RBR1 is used. If the word length is larger than 16 bits,

RBR2 and RBR1 are used and RBR2 contains the most significant bits.

5. The McBSP copies the contents of the receive buffer register(s) into the data receive register(s), provided that DRR1 is not full with previous data. When DRR1 receives new data, the receiver ready bit (RRDY) is set in SPCR1. This indicates that received data is ready to be read by the CPU or the DMA controller.

   If the word length is 16 bits or smaller, only DRR1 is used. If the word length is larger than 16 bits, DRR2 and DRR1 are used and DRR2 contains the most significant bits.
   If companding is used during the copy (RCOMPAND = 10b or 11b in RCR2), the 8-bit compressed data in RBR1 is expanded to a left-justified 16-bit value in DRR1. If companding is disabled, the data copied from RBR[1,2] to DRR[1,2] is justified and bit filled according to the RJUST bits.

6. The CPU or the DMA controller reads the data from the data receive register(s). When DRR1 is read, RRDY is cleared and the next RBR-to-DRR copy is initiated.

NOTE: If both DRRs are required (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.

When activity is not properly timed, errors can occur. See the following topics for more details:

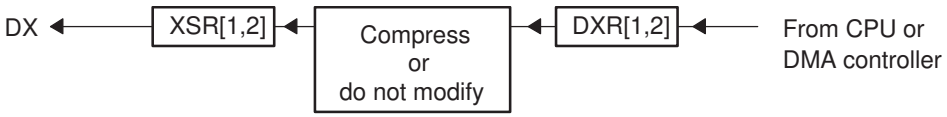
- *Overrun in the Receiver* (see Section 34.5.2)
- *Unexpected Receive Frame-Synchronization Pulse* (see Section 34.5.3)

34.3.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP. For details about how to program the McBSP transmitter, see Section 34.9.

Figure 34-15 and Figure 34-16 show how transmission occurs in the McBSP. Figure 34-15 shows the physical path for the data. Figure 34-16 is a timing diagram showing signal activity for one possible transmission scenario. A description of the process follows the figures.

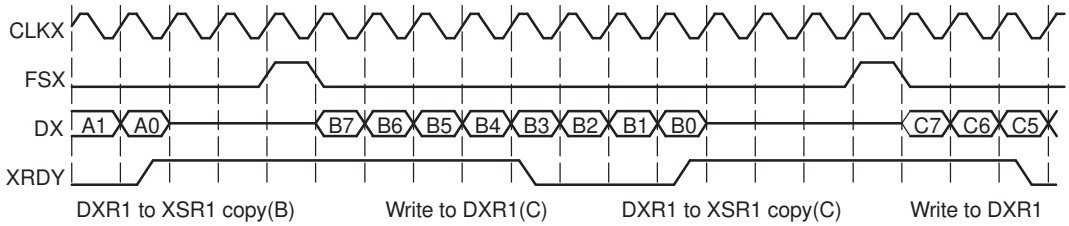
Figure 34-15. McBSP Transmission Physical Data Path



A XSR[1,2]: Transmit shift registers 1 and 2

B DXR[1,2]: Data transmit registers 1 and 2

Figure 34-16. McBSP Transmission Signal Activity



A CLKX: Internal transmit clock

B FSX: Internal transmit frame-synchronization signal

C DX: Data on DX pin

D XRDY: Status of transmitter ready bit (high is 1)

1. The CPU or the DMA controller writes data to the data transmit register(s). When DXR1 is loaded, the transmitter ready bit (XRDY) is cleared in SPCR2 to indicate that the transmitter is not ready for new data.

   If the word length is 16 bits or smaller, only DXR1 is used. If the word length is larger than 16 bits, DXR2 and DXR1 are used and DXR2 contains the most significant bits. For details on choosing a word

length, see Section 34.9.9.

NOTE: If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs), as described in the next step. If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

2. When new data arrives in DXR1, the McBSP copies the content of the data transmit register(s) to the transmit shift register(s). In addition, the transmit ready bit (XRDY) is set. This indicates that the transmitter is ready to accept new data from the CPU or the DMA controller.

   If the word length is 16 bits or smaller, only XSR1 is used. If the word length is larger than 16 bits, XSR2 and XSR1 are used and XSR2 contains the most significant bits.

   If companding is used during the transfer (XCOMPAND = 10b or 11b in XCR2), the McBSP compresses the 16-bit data in DXR1 to 8-bit data in the μ-law or A-law format in XSR1. If companding is disabled, the McBSP passes data from the DXR(s) to the XSR(s) without modification.
3. The McBSP waits for a transmit frame-synchronization pulse on internal FSX.
4. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the XDATDLY bits of XCR2.

   In the preceding timing diagram (Figure 34-16), a 1-bit data delay is selected.
5. The McBSP shifts data bits from the transmit shift register(s) to the DX pin.

When activity is not properly timed, errors can occur. See the following topics for more details:

- *Overwrite in the Transmitter* (Section 34.5.4)
- *Underflow in the Transmitter* (Section 34.5.5)
- *Unexpected Transmit Frame-Synchronization Pulse* (Section 34.5.6)

34.3.7 Interrupts and DMA Events Generated by a McBSP

The McBSP sends notification of important events to the CPU and DMA via the internal signals shown in Table 34-3.

Table 34-3. Interrupts and DMA Events Generated by a McBSP

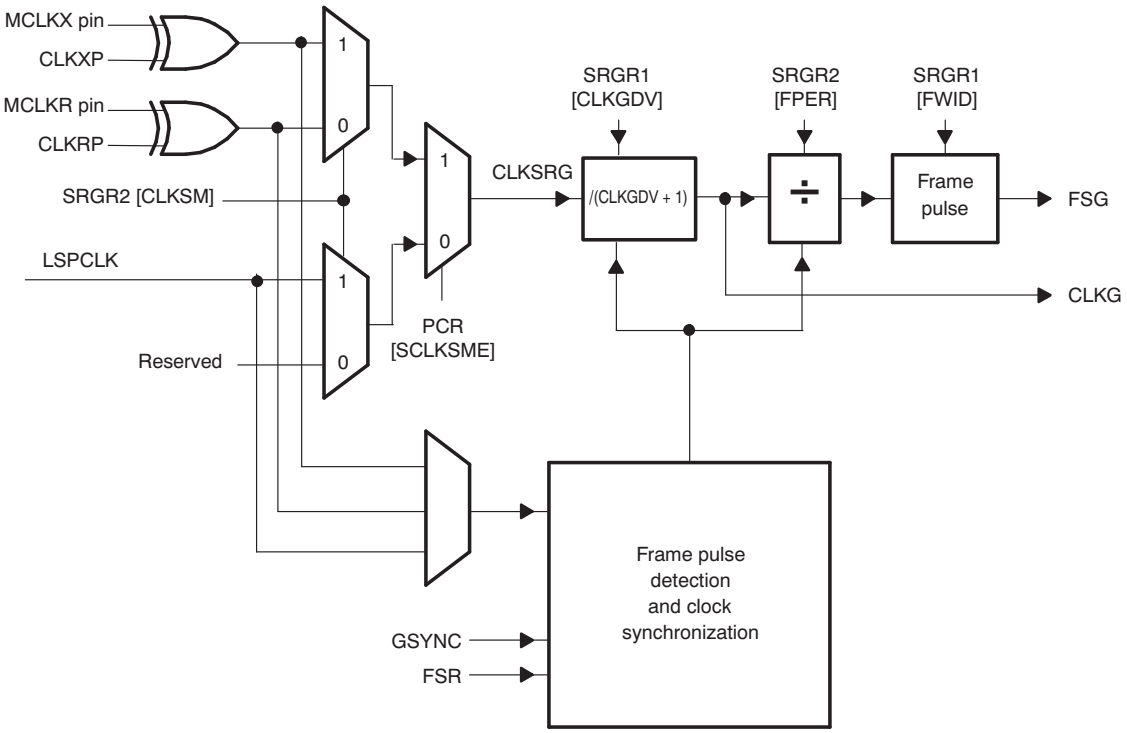
Internal Signal	Description
RINT	Receive interrupt
	The McBSP sends a receive interrupt request to the CPU based upon a selected condition in the receiver of the McBSP (a condition selected by the RINTM bits of SPCR1).
XINT	Transmit interrupt
	The McBSP sends a transmit interrupt request to the CPU based upon a selected condition in the transmitter of the McBSP (a condition selected by the XINTM bits of SPCR2).
REVT	Receive synchronization event
	An REVT signal is sent to the DMA when data has been received in the data receive registers (DRRs).
XEVT	Transmit synchronization event
	An XEVT signal is sent to the DMA when the data transmit registers (DXRs) are ready to accept the next serial word for transmission.

34.4 McBSP Sample Rate Generator

Each McBSP contains a sample rate generator (SRG) that can be programmed to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive (DR) pin and/or the data transmit (DX) pin. FSG can be used to initiate frame transfers on DR and/or DX. Figure 34-17 is a conceptual block diagram of the sample rate generator.

34.4.1 Block Diagram

Figure 34-17. Conceptual Block Diagram of the Sample Rate Generator



The source clock for the sample rate generator (labeled CLKSRG in the diagram) can be supplied by the LSPCLK, or by an external pin (MCLKX or MCLKR). The source is selected with the SCLKME bit of PCR and the CLKSM bit of SRGR2. If a pin is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (CLKXP of PCR or CLKRP of PCR).

The sample rate generator has a three-stage clock divider that gives CLKG and FSG programmability. The three stages provide:

- Clock divide-down. The source clock is divided according to the CLKGDV bits of SRGR1 to produce CLKG.
- Frame period divide-down. CLKG is divided according to the FPER bits of SRGR2 to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-synchronization pulse-width countdown. CLKG cycles are counted according to the FWID bits of SRGR1 to control the width of each frame-synchronization pulse.

NOTE: The McBSP cannot operate at a frequency faster than ½ the source clock frequency. You must choose an input clock frequency and a CLKGDV value such that CLKG is less than or equal to ½ the source clock frequency.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the FSR pin. This feature is enabled or disabled with the GSYNC bit of SRGR2.

For details on getting the sample rate generator ready for operation, see Section 34.4.4.

34.4.1.1 Clock Generation in the Sample Rate Generator

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the sample rate generator to drive clocking is controlled by the clock mode bits (CLKRM and CLKXM) in the pin control register (PCR). When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal sample rate generator output clock (CLKG).

The effects of CLKRM = 1 and CLKXM = 1 on the McBSP are partially affected by the use of the digital loopback mode and the clock stop (SPI) mode, respectively, as described in Table 34-4. The digital loopback mode (described in Section 34.8.4) is selected with the DLB bit of SPCR1. The clock stop mode (described in Section 34.7.2) is selected with the CLKSTP bits of SPCR1.

When using the sample rate generator as a clock source, make sure the sample rate generator is enabled (GRST = 1).

Table 34-4. Effects of DLB and CLKSTP on Clock Modes

Mode Bit Settings		Effect
CLKRM = 1	DLB = 0 (Digital loopback mode disabled)	CLKR is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 1 (Digital loopback mode enabled)	CLKR is an output pin driven by internal CLKX. The source for CLKX depends on the CLKXM bit.
CLKXM = 1	CLKSTP = 00b or 01b (Clock stop (SPI) mode disabled)	CLKX is an output pin driven by the sample rate generator output clock (CLKG).
	CLKSTP = 10b or 11b (Clock stop (SPI) mode enabled)	The McBSP is a master in an SPI system. Internal CLKX drives internal CLKR and the shift clocks of any SPI-compliant slave devices in the system. CLKX is driven by the internal sample rate generator.

34.4.1.2 Choosing an Input Clock

The sample rate generator must be driven by an input clock signal from one of the three sources selectable with the SCLKME bit of PCR and the CLKSM bit of SRGR2 (see Table 34-5). When CLKSM = 1, the minimum divide down value in CLKGDV bits is 1. CLKGDV is described in Section 34.4.1.4.

Table 34-5. Choosing an Input Clock for the Sample Rate Generator with the SCLKME and CLKSM Bits

SCLKME	CLKSM	Input Clock for Sample Rate Generator
0	0	Reserved
0	1	LSPCLK
1	0	Signal on MCLKR pin
1	1	Signal on MCLKX pin

34.4.1.3 Choosing a Polarity for the Input Clock

As shown in Figure 34-18, when the input clock is received from a pin, you can choose the polarity of the input clock. The rising edge of CLKSRG generates CLKG and FSG, but you can determine which edge of the input clock causes a rising edge on CLKSRG. The polarity options and their effects are described in Table 34-6.

Figure 34-18. Possible Inputs to the Sample Rate Generator and the Polarity Bits

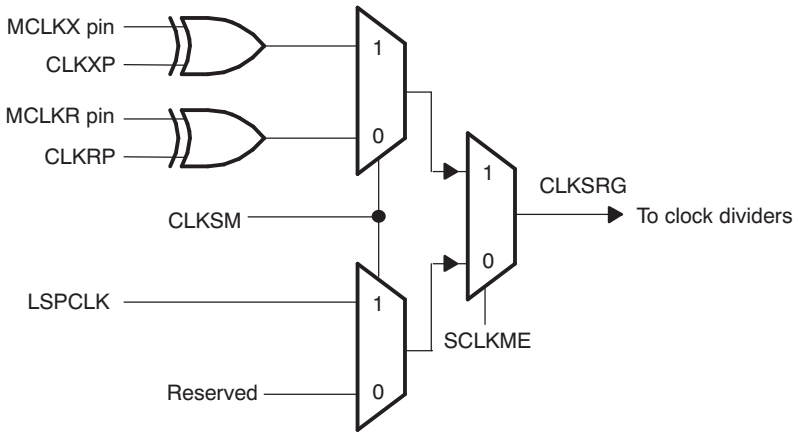


Table 34-6. Polarity Options for the Input to the Sample Rate Generator

Input Clock	Polarity Option	Effect
LSPCLK	Always positive polarity	Rising edge of CPU clock generates transitions on CLKG and FSG.
Signal on MCLKR pin	CLKRP = 0 in PCR	Falling edge on MCLKR pin generates transitions on CLKG and FSG.
	CLKRP = 1 in PCR	Rising edge on MCLKR pin generates transitions on CLKG and FSG.
Signal on MCLKX pin	CLKXP = 0 in PCR	Rising edge on MCLKX pin generates transitions on CLKG and FSG.
	CLKXP = 1 in PCR	Falling edge on MCLKX pin generates transitions on CLKG and FSG.

34.4.1.4 Choosing a Frequency for the Output Clock (CLKG)

The input clock (LSPCLK or external clock) can be divided down by a programmable value to drive CLKG. Regardless of the source to the sample rate generator, the rising edge of CLKSRG (see Figure 34-1) generates CLKG and FSG.

The first divider stage of the sample rate generator creates the output clock from the input clock. This divider stage uses a counter that is preloaded with the divide down value in the CLKGDV bits of SRGR1. The output of this stage is the data clock (CLKG). CLKG has the frequency represented by the equation below.

Equation 1: CLKG Frequency

$$\text{CLKG frequency} = \frac{\text{Input clock frequency}}{(\text{CLKGDV} + 1)}$$

34.4.1.4.1 CLKG Frequency

Thus, the input clock frequency is divided by a value between 1 and 256. When CLKGDV is odd or equal to 0, the CLKG duty cycle is 50%. When CLKGDV is an even value, 2p, representing an odd divide down, the high-state duration is p+1 cycles and the low-state duration is p cycles.

34.4.1.5 Keeping CLKG Synchronized to External MCLKR

When the MCLKR pin is used to drive the sample rate generator (see Section 34.4.1.2), the GSYNC bit in SRGR2 and the FSR pin can be used to configure the timing of the output clock (CLKG) relative to the input clock. Note that this feature is available only when the MCLKR pin is used to feed the external clock.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and generation of FSG.

For more details about synchronization, see Section 34.4.3.

34.4.2 Frame Synchronization Generation in the Sample Rate Generator

The sample rate generator can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure FSRM = 1. (When FSRM = 0, receive frame synchronization is supplied via the FSR pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- FSXM = 1 in PCR: This indicates that transmit frame synchronization is supplied by the McBSP itself rather than from the FSX pin.
- FSGM = 1 in SRGR2: This indicates that when FSXM = 1, transmit frame synchronization is supplied by the sample rate generator. (When FSGM = 0 and FSXM = 1, the transmitter uses frame-synchronization pulses generated every time data is transferred from DXR[1,2] to XSR[1,2].)

In either case, the sample rate generator must be enabled (GRST = 1) and the frame-synchronization logic in the sample rate generator must be enabled (FRST = 1).

34.4.2.1 Choosing the Width of the Frame-Synchronization Pulse on FSG

Each pulse on FSG has a programmable width. You program the FWID bits of SRGR1, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

34.4.2.2 Controlling the Period Between the Starting Edges of Frame-Synchronization Pulses on FSG

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the sample rate generator:

- If the sample rate generator is using an external input clock and GSYNC = 1 in SRGR2, FSG pulses in response to an inactive-to-active transition on the FSR pin. Thus, the frame-synchronization period is controlled by an external device.
- Otherwise, you program the FPER bits of SRGR2, and the resulting frame-synchronization period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

34.4.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the sample rate generator (see Section 34.4.1.2) , the GSYNC bit of SRGR2 and the FSR pin can be used to configure the timing of FSG pulses.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and generation of FSG.

See Section 34.4.3 for more details about synchronization.

34.4.3 Synchronizing Sample Rate Generator Outputs to an External Clock

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) based on an input clock signal that is either the CPU clock signal or a signal at the MCLKR or MCLKX pin. When an external clock is selected to drive the sample rate generator, the GSYNC bit of SRGR2 and the FSR pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock.

Make GSYNC = 1 when you want the McBSP and an external device to divide down the input clock with the same phase relationship. If GSYNC = 1:

- An inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and a pulsing of FSG.
- CLKG always begins with a high state after synchronization.
- FSR is always detected at the same edge of the input clock signal that generates CLKG, no matter how long the FSR pulse is.
- The FPER bits of SRGR2 are ignored because the frame-synchronization period on FSG is determined

by the arrival of the next frame-synchronization pulse on the FSR pin.

If GSYNC = 0, CLKG runs freely and is not resynchronized, and the frame-synchronization period on FSG is determined by FPER.

34.4.3.1 Operating the Transmitter Synchronously with the Receiver

When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that:

- FSX is programmed to be driven by FSG (FSGM = 1 in SRGR2 and FSXM = 1 in PCR). If the input FSR has appropriate timing so that it can be sampled by the falling edge of CLKG, it can be used, instead, by setting FSXM = 0 and connecting FSR to FSX externally.
- The sample rate generator clock drives the transmit and receive clocking (CLKRM = CLKXM = 1 in PCR).

34.4.3.2 Synchronization Examples

Figure 34-19 and Figure 34-20 show the clock and frame-synchronization operation with various polarities of CLKR and FSR. These figures assume FWID = 0 in SRGR1, for an FSG pulse that is one CLKG cycle wide. The FPER bits of SRGR2 are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the FSR pin. Each of the figures shows what happens to CLKG when it is initially synchronized and GSYNC = 1, and when it is not initially synchronized and GSYNC = 1. Figure 34-20 has a slower CLKG frequency (it has a larger divide-down value in the CLKGDV bits of SRGR1).

Figure 34-19. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 1

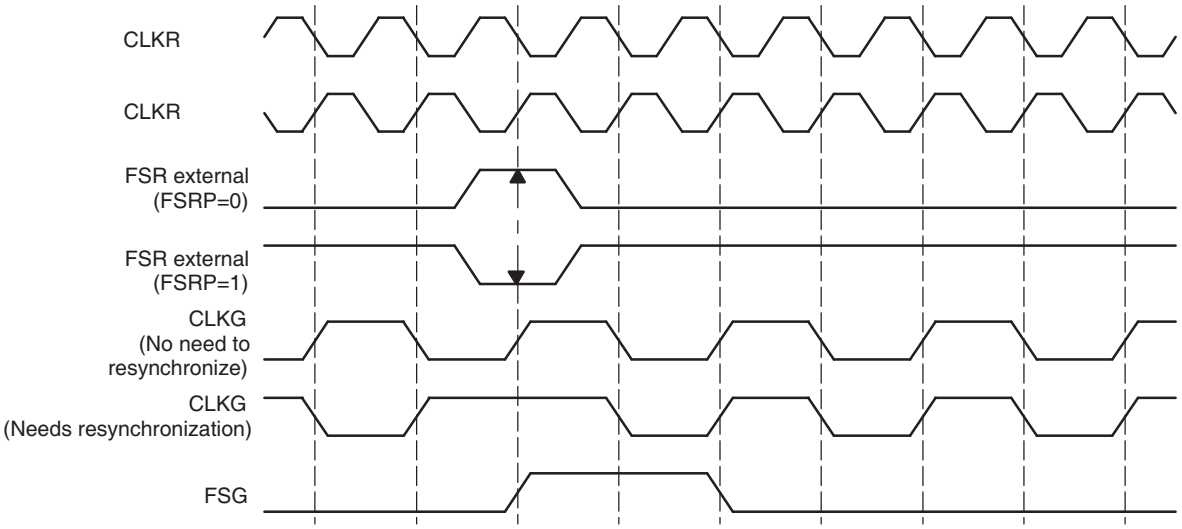

Figure 34-20. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 3

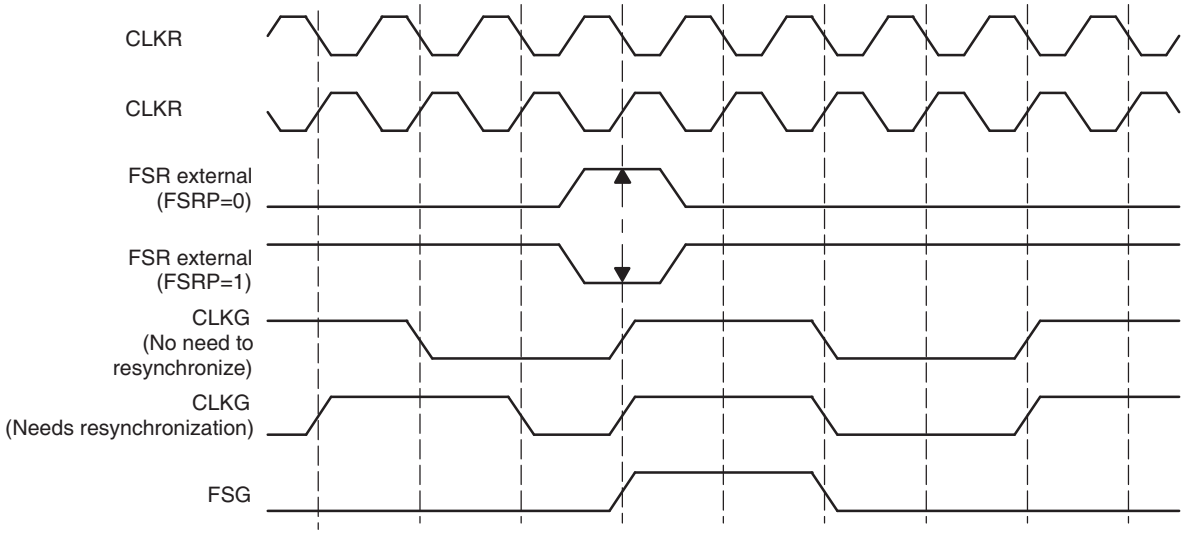


34.4.4 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the sample rate generator:

Step 1. Place the McBSP/sample rate generator in reset.

During a DSP reset, the sample rate generator, the receiver, and the transmitter reset bits (GRST, RRST, and XRST) are automatically forced to 0. Otherwise, during normal operation, the sample rate generator can be reset by seting GRST = 0 in SPCR2, provided that CLKG and/or FSG is not used by any portion of the McBSP. Depending on your system you may also want to reset the receiver (RRST = 0 in SPCR1) and reset the transmitter (XRST = 0 in SPCR2).

If GRST = 0 due to a device reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven inactive-low. If GRST = 0 due to program code, CLKG and FSG are driven low (inactive).

Step 2. Program the registers that affect the sample rate generator.

Program the sample rate generator registers (SRGR1 and SRGR2) as required for your application. If necessary, other control registers can be loaded with desired values, provided the respective portion of the McBSP (the receiver or transmitter) is in reset.

After the sample rate generator registers are programmed, wait 2 CLKSRG cycles. This ensures proper synchronization internally.

Step 3. Enable the sample rate generator (take it out of reset).

In SPCR2, make GRST = 1 to enable the sample rate generator.

After the sample rate generator is enabled, wait two CLKG cycles for the sample rate generator logic to stabilize.

On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to the CLKG Frequency equation below.

Table 34-7. Input Clock Selection for Sample Rate Generator

SCLKME	CLKSM	Input Clock for Sample Rate Generator
0	0	Reserved
0	1	LSPCLK
1	0	Signal on MCLKR pin
1	1	Signal on MCLKX pin

Step 4. If necessary, enable the receiver and/or the transmitter.

If necessary, remove the receiver and/or transmitter from reset by setting RRST and/or XRST = 1.

Step 5. If necessary, enable the frame-synchronization logic of the sample rate generator.

After the required data acquisition setup is done (DXR[1,2] is loaded with data), set GRST = 1 in SPCR2 if an internally generated frame-synchronization pulse is required. FSG is generated with an active-high edge after the programmed number of CLKG clocks (FPER + 1) have elapsed.

Equation 2: CLKG Frequency

$$\text{CLKG frequency} = \frac{\text{Input clock frequency}}{(\text{CLKGDV} + 1)}$$

where the input clock is selected with the SCLKME bit of PCR and the CLKSM bit of SRGR2 in one of the configurations shown in Table 34-7.

34.5 McBSP Exception/Error Conditions

This chapter describes exception/error conditions and how to handle them.

34.5.1 Types of Errors

There are five serial port events that can constitute a system error:

- Receiver overrun (RFULL = 1)

  This error occurs when DRR1 has not been read since the last RBR-to-DRR copy. Consequently, the receiver does not copy a new word from the RBR(s) to the DRR(s) and the RSR(s) are now full with another new word shifted in from DR. Therefore, RFULL = 1 indicates an error condition wherein any new data that can arrive at this time on DR replaces the contents of the RSR(s), and the previous word is lost. The RSRs continue to be overwritten as long as new data arrives on DR and DRR1 is not read. For more details about overrun in the receiver, see Section 34.5.2.

- Unexpected receive frame-synchronization pulse (RSYNCERR = 1)

  This error occurs during reception when RFIG = 0 and an unexpected frame-synchronization pulse occurs. An unexpected frame-synchronization pulse is one that begins the next frame transfer before all the bits of the current frame have been received. Such a pulse causes data reception to abort and restart. If new data has been copied into the RBR(s) from the RSR(s) since the last RBR-to-DRR copy, this new data in the RBR(s) is lost. This is because no RBR-to-DRR copy occurs; the reception has been restarted. For more details about receive frame-synchronization errors, see Section 34.5.3.

- Transmitter data overwrite

  This error occurs when the CPU or DMA controller overwrites data in the DXR(s) before the data is copied to the XSR(s). The overwritten data never reaches the DX pin. For more details about overwrite in the transmitter, see Section 34.5.4.

- Transmitter underflow ($\overline{\text{XEMPTY}}$ = 0)

  If a new frame-synchronization signal arrives before new data is loaded into DXR1, the previous data in the DXR(s) is sent again. This procedure continues for every new frame-synchronization pulse that arrives until DXR1 is loaded with new data. For more details about underflow in the transmitter, see Section 34.5.5.

- Unexpected transmit frame-synchronization pulse (XSYNCERR = 1)

  This error occurs during transmission when XFIG = 0 and an unexpected frame-synchronization pulse occurs. An unexpected frame-synchronization pulse is one that begins the next frame transfer before all the bits of the current frame have been transferred. Such a pulse causes the current data transmission to abort and restart. If new data has been written to the DXR(s) since the last DXR-to-XSR copy, the current value in the XSR(s) is lost. For more details about transmit frame-synchronization errors, see Section 34.5.6.

34.5.2 Overrun in the Receiver

RFULL = 1 in SPCR1 indicates that the receiver has experienced overrun and is in an error condition. RFULL is set when all of the following conditions are met:

1. DRR1 has not been read since the last RBR-to-DRR copy (RRDY = 1).
2. RBR1 is full and an RBR-to-DRR copy has not occurred.
3. RSR1 is full and an RSR1-to-RBR copy has not occurred.

As described in Section 34.3.5, data arriving on DR is continuously shifted into RSR1 (for word length of 16 bits or smaller) or RSR2 and RSR1 (for word length larger than 16 bits). Once a complete word is shifted into the RSR(s), an RSR-to-RBR copy can occur only if the previous data in RBR1 has been copied to DRR1. The RRDY bit is set when new data arrives in DRR1 and is cleared when that data is read from DRR1. Until RRDY = 0, the next RBR-to-DRR copy does not take place, and the data is held in the RSR(s). New data arriving on the DR pin is shifted into RSR(s), and the previous content of the RSR(s) is lost.

You can prevent the loss of data if DRR1 is read no later than 2.5 cycles before the end of the third word is shifted into the RSR1.

NOTE: If both DRRs are needed (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.

After the receiver starts running from reset, a minimum of three words must be received before RFULL is set. Either of the following events clears the RFULL bit and allows subsequent transfers to be read properly:

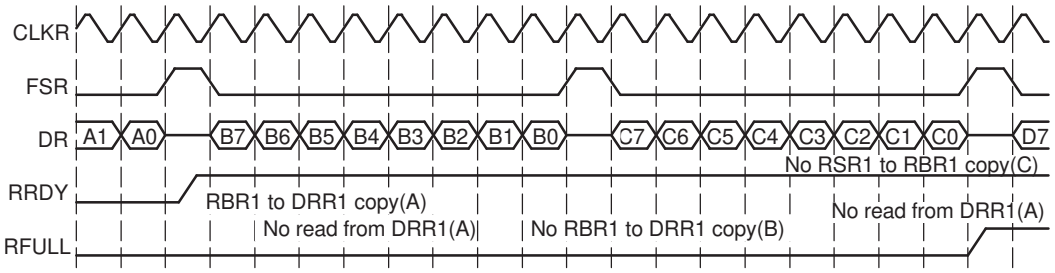
- The CPU or DMA controller reads DRR1.
- The receiver is reset individually (RRST = 0) or as part of a device reset.

Another frame-synchronization pulse is required to restart the receiver.

34.5.2.1 Example of Overrun Condition

Figure 34-21 shows the receive overrun condition. Because serial word A is not read from DRR1 before serial word B arrives in RBR1, B is not transferred to DRR1 yet. Another new word ©) arrives and RSR1 is full with this data. DRR1 is finally read, but not earlier than 2.5 cycles before the end of word C. Therefore, new data (D) overwrites word C in RSR1. If DRR1 is not read in time, the next word can overwrite D.

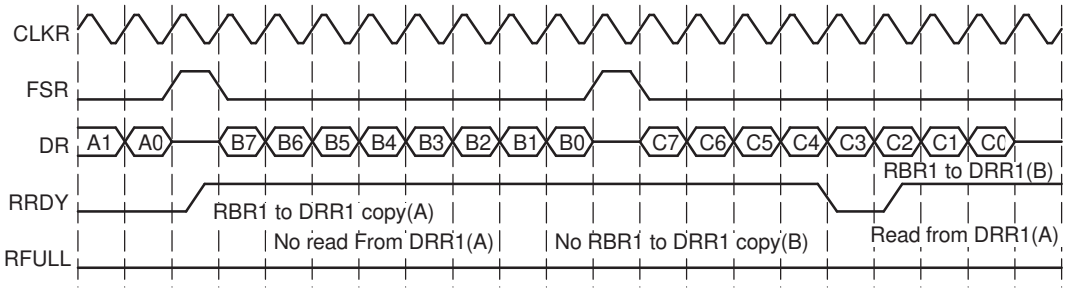
Figure 34-21. Overrun in the McBSP Receiver



34.5.2.2 Example of Preventing Overrun Condition

Figure 34-22 shows the case where RFULL is set, but the overrun condition is prevented by a read from DRR1 at least 2.5 cycles before the next serial word ©) is completely shifted into RSR1. This ensures that an RBR1-to-DRR1 copy of word B occurs before receiver attempts to transfer word C from RSR1 to RBR1.

Figure 34-22. Overrun Prevented in the McBSP Receiver



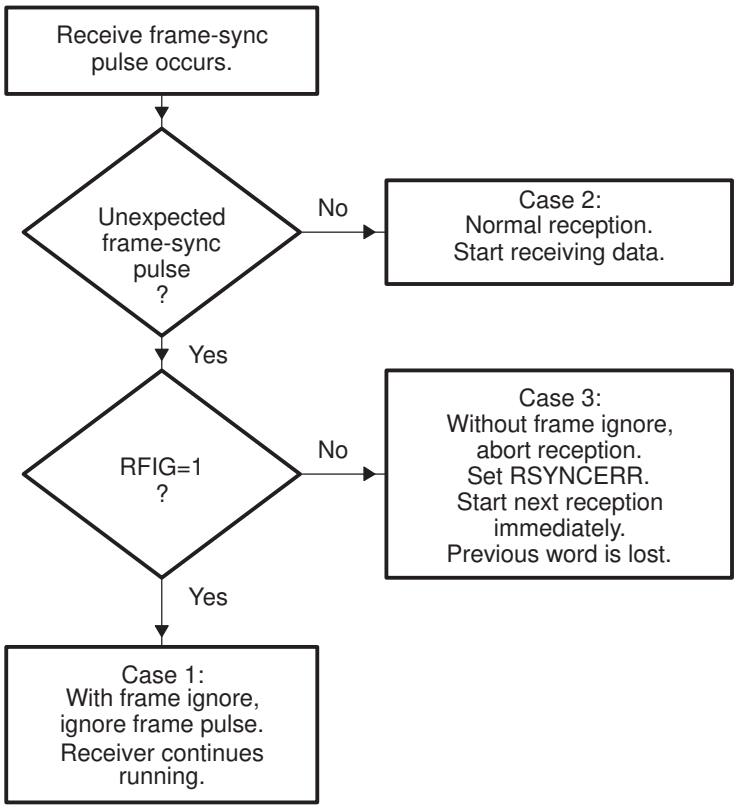
34.5.3 Unexpected Receive Frame-Synchronization Pulse

Section 34.5.3.1 shows how the McBSP responds to any receive frame-synchronization pulses, including an unexpected pulse. Section 34.5.3.2 and Section 34.5.3.3 show an example of a frame-synchronization error and an example of how to prevent such an error, respectively.

34.5.3.1 Possible Responses to Receive Frame-Synchronization Pulses

Figure 34-23 shows the decision tree that the receiver uses to handle all incoming frame-synchronization pulses. The figure assumes that the receiver has been started (RRST = 1 in SPCR1). Case 3 shows where an error occurs.

Figure 34-23. Possible Responses to Receive Frame-Synchronization Pulses



Any one of three cases can occur:

- Case 1: Unexpected internal FSR pulses with RFIG = 1 in RCR2. Receive frame-synchronization pulses are ignored, and the reception continues.
- Case 2: Normal serial port reception. Reception continues normally because the frame-synchronization pulse is not unexpected. There are three possible reasons why a receive operation might *not* be in

progress when the pulse occurs:

- The FSR pulse is the first after the receiver is enabled (RRST = 1 in SPCR1).
- The FSR pulse is the first after DRR[1,2] is read, clearing a receiver full (RFULL = 1 in SPCR1) condition.
- The serial port is in the interpacket intervals. The programmed data delay for reception (programmed with the RDATDLY bits in RCR2) may start during these interpacket intervals for the first bit of the next word to be received. Thus, at maximum frame frequency, frame synchronization can still be received 0 to 2 clock cycles before the first bit of the synchronized frame.

- Case 3: Unexpected receive frame synchronization with RFIG = 0 (frame-synchronization pulses not ignored). Unexpected frame-synchronization pulses can originate from an external source or from the internal sample rate generator.

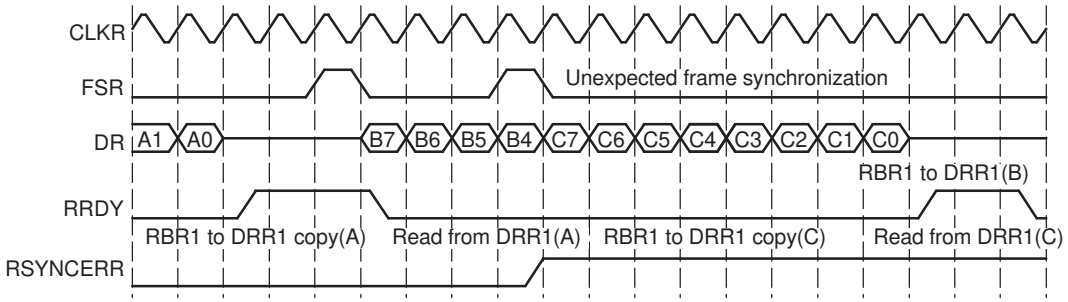
  If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit (RSYNCERR) in SPCR1. RSYNCERR can be cleared only by a receiver reset or by a write of 0 to this bit.

  If you want the McBSP to notify the CPU of receive frame-synchronization errors, you can set a special receive interrupt mode with the RINTM bits of SPCR1. When RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU each time that RSYNCERR is set.

34.5.3.2 Example of Unexpected Receive Frame-Synchronization Pulse

Figure 34-30 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets. When the unexpected frame-synchronization pulse occurs, the RSYNCERR bit is set, the reception of data B is aborted, and the reception of data C begins. In addition, if RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU.

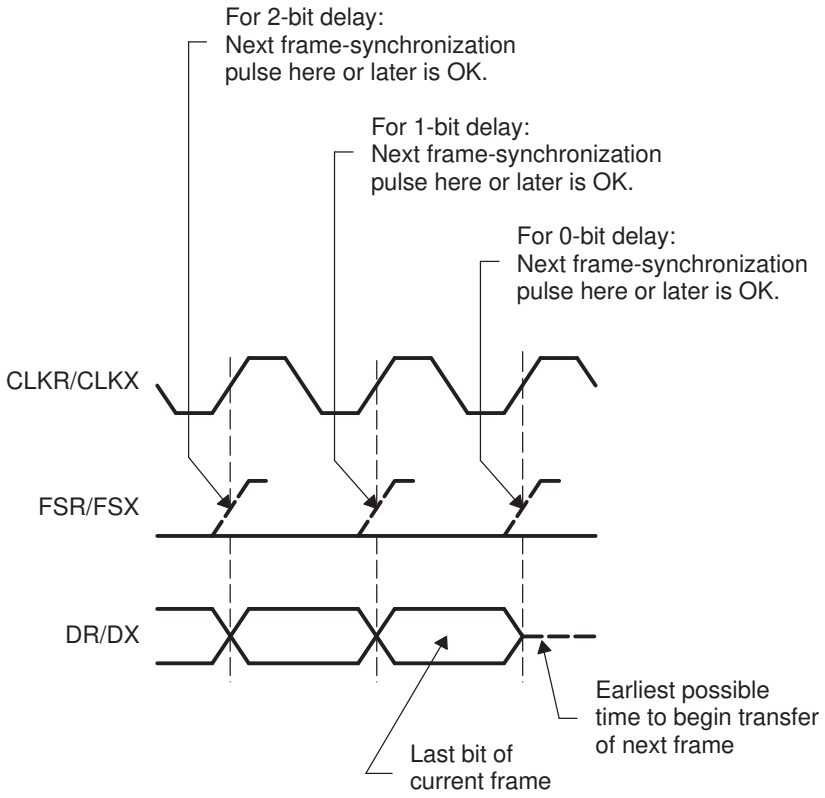
Figure 34-24. An Unexpected Frame-Synchronization Pulse During a McBSP Reception



34.5.3.3 Preventing Unexpected Receive Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 MCLKR cycles, depending on the value in the RDATDLY bits of RCR2. For each possible data delay, Figure 34-25 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 34-25. Proper Positioning of Frame-Synchronization Pulses



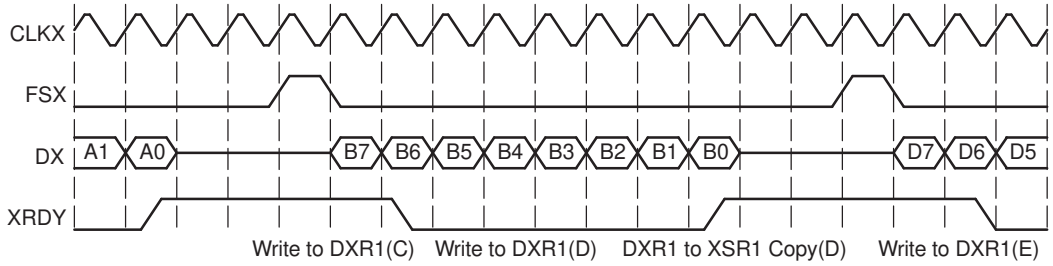
34.5.4 Overwrite in the Transmitter

As described in Section 34.3.6), the transmitter must copy the data previously written to the DXR(s) by the CPU or DMA controller into the XSR(s) and then shift each bit from the XSR(s) to the DX pin. If new data is written to the DXR(s) before the previous data is copied to the XSR(s), the previous data in the DXR(s) is overwritten and thus lost.

34.5.4.1 Example of Overwrite Condition

Figure 34-26 shows what happens if the data in DXR1 is overwritten before being transmitted. Initially, DXR1 is loaded with data C. A subsequent write to DXR1 overwrites C with D before C is copied to XSR1. Thus, C is never transmitted on DX.

Figure 34-26. Data in the McBSP Transmitter Overwritten and Thus Not Transmitted



34.5.4.2 Preventing Overwrites

You can prevent CPU overwrites by making the CPU:

- Poll for XRDY = 1 in SPCR2 before writing to the DXR(s). XRDY is set when data is copied from DXR1 to XSR1 and is cleared when new data is written to DXR1.

- Wait for a transmit interrupt (XINT) before writing to the DXR(s). When XINTM = 00b in SPCR2, the transmitter sends XINT to the CPU each time XRDY is set.

You can prevent DMA overwrites by synchronizing DMA transfers to the transmit synchronization event XEVT. The transmitter sends an XEVT signal each time XRDY is set.

34.5.5 Underflow in the Transmitter

The McBSP indicates a transmitter empty (or underflow) condition by clearing the $\overline{\text{XEMPTY}}$ bit in SPCR2. Either of the following events activates $\overline{\text{XEMPTY}}$ ($\overline{\text{XEMPTY}}$ = 0):

- DXR1 has not been loaded since the last DXR-to-XSR copy, and all bits of the data word in the XSR(s) have been shifted out on the DX pin.
- The transmitter is reset (by forcing XRST = 0 in SPCR2, or by a device reset) and is then restarted.

In the underflow condition, the transmitter continues to transmit the old data that is in the DXR(s) for every new transmit frame-synchronization signal, until a new value is loaded into DXR1 by the CPU or the DMA controller.

NOTE: If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs). If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

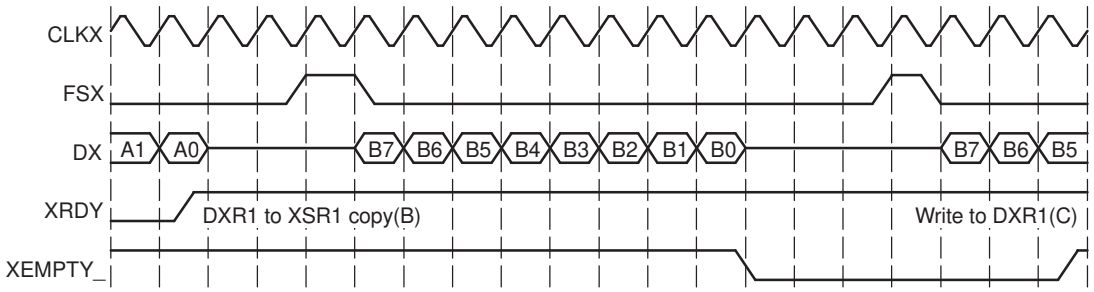
XEMPTY is deactivated (XEMPTY = 1) when a new word in DXR1 is transferred to XSR1. If FSXM = 1 in PCR and FSGM = 0 in SRGR2, the transmitter generates a single internal FSX pulse in response to a DXR-to-XSR copy. Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on DX.

When the transmitter is taken out of reset (XRST = 1), it is in a transmitter ready (XRDY = 1 in SPCR2) and transmitter empty (XEMPTY = 0) state. If DXR1 is loaded by the CPU or the DMA controller before internal FSX goes active high, a valid DXR-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before DXR1 is loaded, zeros are output on DX.

34.5.5.1 Example of the Underflow Condition

Figure 34-27 shows an underflow condition. After B is transmitted, DXR1 is not reloaded before the subsequent frame-synchronization pulse. Thus, B is again transmitted on DX.

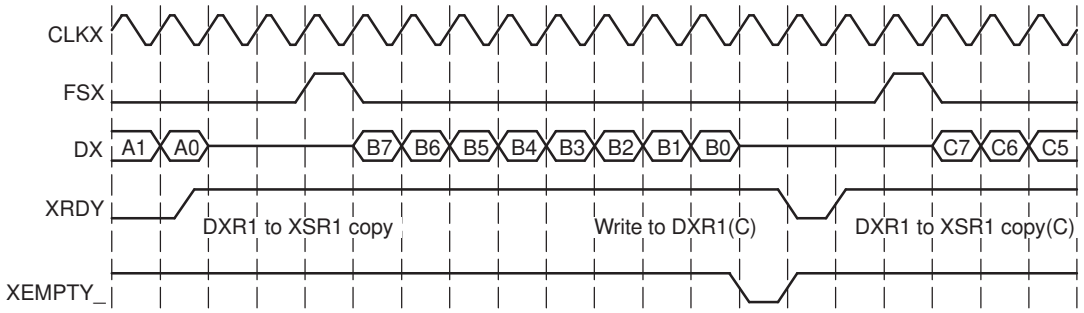
Figure 34-27. Underflow During McBSP Transmission



34.5.5.2 Example of Preventing Underflow Condition

Figure 34-28 shows the case of writing to DXR1 just before an underflow condition would otherwise occur. After B is transmitted, C is written to DXR1 before the next frame-synchronization pulse. As a result, there is no underflow; B is not transmitted twice.

Figure 34-28. Underflow Prevented in the McBSP Transmitter



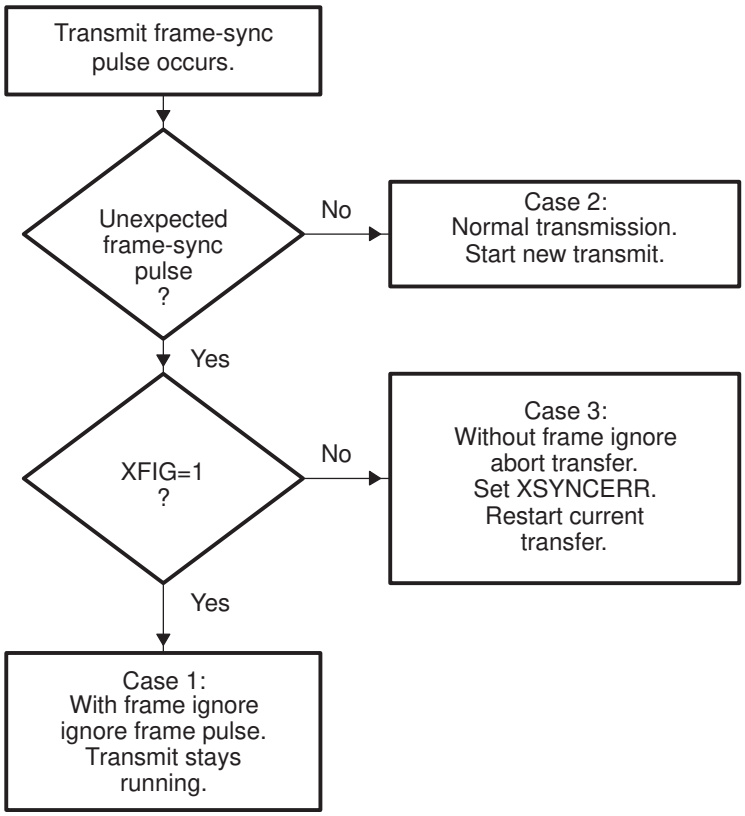
34.5.6 Unexpected Transmit Frame-Synchronization Pulse

Section 34.5.6.1 shows how the McBSP responds to any transmit frame-synchronization pulses, including an unexpected pulse. Section 34.5.6.2 and Section 34.5.6.3 show examples of a frame-synchronization error and an example of how to prevent such an error, respectively.

34.5.6.1 Possible Responses to Transmit Frame-Synchronization Pulses

Figure 34-29 shows the decision tree that the transmitter uses to handle all incoming frame-synchronization pulses. The figure assumes that the transmitter has been started (XRST = 1 in SPCR2). Case 3 shows where an error occurs.

Figure 34-29. Possible Responses to Transmit Frame-Synchronization Pulses



Any one of three cases can occur:

- Case 1: Unexpected internal FSX pulses with XFIG = 1 in XCR2. Transmit frame-synchronization pulses are ignored, and the transmission continues.
- Case 2: Normal serial port transmission. Transmission continues normally because the frame-

synchronization pulse is not unexpected. There are two possible reasons why a transmit operations might *not* be in progress when the pulse occurs:

This FSX pulse is the first after the transmitter is enabled (XRST = 1).

The serial port is in the interpacket intervals. The programmed data delay for transmission (programmed with the XDATDLY bits of XCR2) may start during these interpacket intervals before the first bit of the previous word is transmitted. Thus, at maximum packet frequency, frame synchronization can still be received 0 to 2 clock cycles before the first bit of the synchronized frame.

- Case 3: Unexpected transmit frame synchronization with XFIG = 0 (frame-synchronization pulses not ignored). Unexpected frame-synchronization pulses can originate from an external source or from the internal sample rate generator.

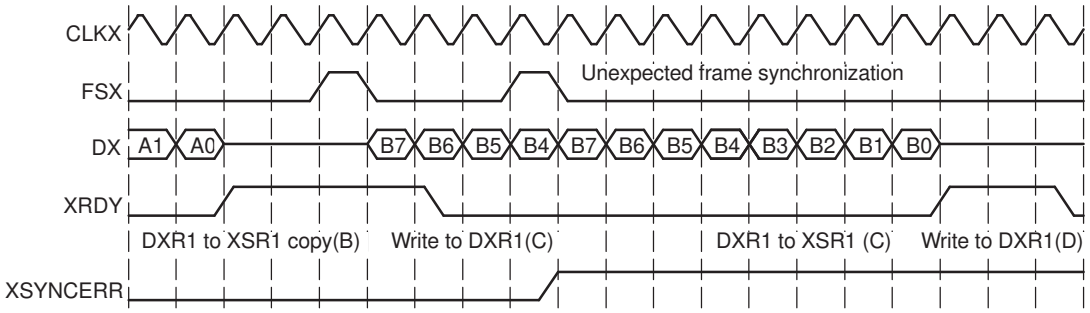
  If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit (XSYNCERR) in SPCR2. XSYNCERR can be cleared only by a transmitter reset or by a write of 0 to this bit.

  If you want the McBSP to notify the CPU of frame-synchronization errors, you can set a special transmit interrupt mode with the XINTM bits of SPCR2. When XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU each time that XSYNCERR is set.

34.5.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Section 34.5.3.2 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets. When the unexpected frame-synchronization pulse occurs, the XSYNCERR bit is set and the transmission of data B is restarted because no new data has been passed to XSR1 yet. In addition, if XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU.

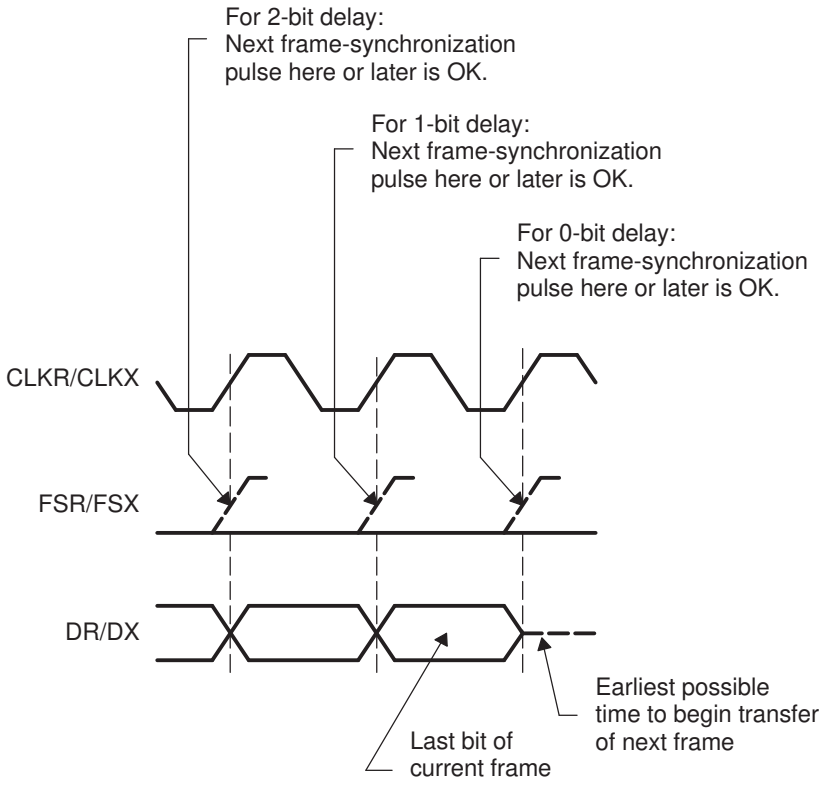
Figure 34-30. An Unexpected Frame-Synchronization Pulse During a McBSP Transmission



34.5.6.3 Preventing Unexpected Transmit Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the XDATDLY bits of XCR2. For each possible data delay, Figure 34-31 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 34-31. Proper Positioning of Frame-Synchronization Pulses



34.6 Multichannel Selection Modes

This section discusses the multichannel selection modes for the McBSP.

34.6.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. Each McBSP supports up to 128 channels for reception and 128 channels for transmission.

In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that each contain 16 contiguous channels (see Table 34-8 through Table 34-10) :

- It is possible to have two receive partitions (A & B) and 8 transmit partitions (A – H).
- McBSP can transmit/receive on selected channels.
- Each channel partition has a dedicated channel-enable register. Each bit controls whether data flow is allowed or prevented in one of the channels assigned to that partition.
- There are three transmit multichannel modes and one receive multichannel mode.

Table 34-8. Block - Channel Assignment

Block	Channels
0	0 -15
1	16 - 31
2	32 - 47
3	48 - 63
4	64 - 79
5	80 - 95
6	96 - 111
7	112 - 127

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode (described in Section 34.6.4), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode (described in Section 34.6.5), blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

Table 34-9. 2-Partition Mode

Partition	Blocks
A	0 or 2 or 4 or 6
B	1 or 3 or 5 or 7

Table 34-10. 8-Partition mode

Partition	Blocks	Channels
A	0	0 -15
B	1	16 - 31
C	2	32 - 47
D	3	48 - 63
E	4	64 - 79
F	5	80 - 95
G	6	96 - 111
H	7	112 - 127

The number of partitions for reception and the number of partitions for transmission are independent. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A-H).

34.6.2 Multichannel Selection

When a McBSP uses a time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP has one receive multichannel selection mode (described in Section 34.6.6) and three transmit multichannel selection modes (described in Section 34.6.7).

34.6.3 Configuring a Frame for Multichannel Selection

Before you enable a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (RPHASE/XPHASE = 0). Each frame represents a TDM data stream.
- Set a frame length (in RFRLEN1/XFRLEN1) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If XFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

34.6.4 Using Two Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions (described in Section 34.6.5). If you choose the 2-partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

34.6.4.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit-channel blocks (up 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

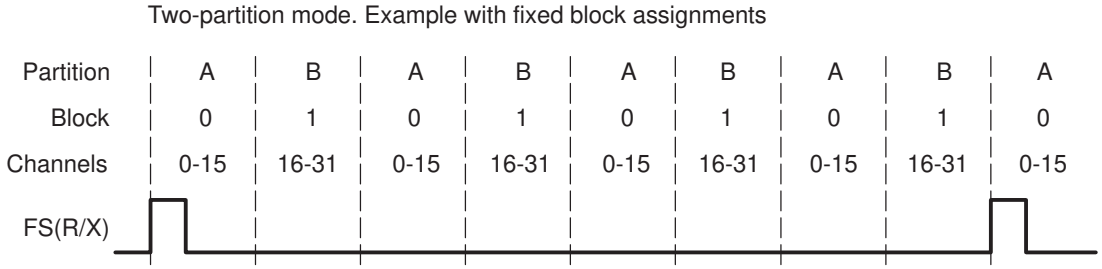
- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bits. In the receive multichannel selection mode (described in Section 34.6.6), the channels in this partition are controlled by receive channel enable register A (RCERA).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (RCERB).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bits. In one of the transmit multichannel selection modes (described in Section 34.6.7), the channels in this partition are controlled by transmit channel enable register A (XCERA).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (XCERB).

Figure 34-32 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0-15 have been assigned to partition A, and channels 16-31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 34-32. Alternating Between the Channels of Partition A and the Channels of Partition B



As explained in Section 34.6.4.2, you can dynamically change which blocks of channels are assigned to the partitions.

34.6.4.2 Reassigning Blocks During Reception/Transmission

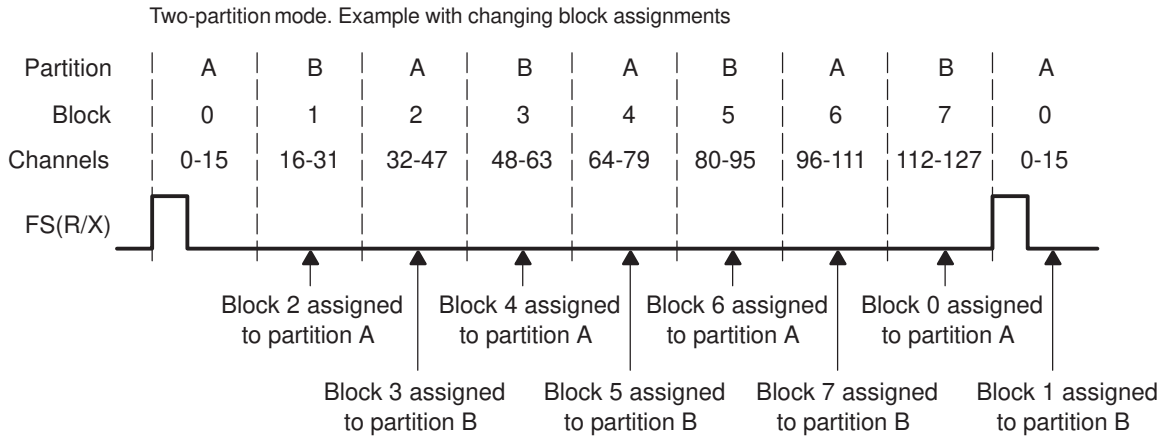
If you want to use more than 32 channels, you can change which channel blocks are assigned to partitions A and B during the course of a data transfer. However, these changes must be carefully timed. While a partition is being transferred, its associated block assignment bits cannot be modified and its associated channel enable register cannot be modified. For example, if block 3 is being transferred and block 3 is assigned to partition A, you cannot modify (R/X)PABLK to assign different channels to partition A, nor (R/X)CERA to change the channel configuration for partition A.

Several features of the McBSP help you time the reassignment:

- The block of channels currently involved in reception/transmission (the current block) is reflected in the RCBLK/XCBLK bits. Your program can poll these bits to determine which partition is active. When a partition is not active, it is safe to change its block assignment and channel configuration.
- At the end of every block (at the boundary of two partitions), an interrupt can be sent to the CPU. In response to the interrupt, the CPU can then check the RCBLK/XCBLK bits and update the inactive partition. See Section 34.6.8.

Figure 34-33 shows an example of reassigning channels throughout a data transfer. In response to a frame-synchronization pulse, the McBSP alternates between partitions A and B. Whenever partition B is active, the CPU changes the block assignment for partition A. Whenever partition A is active, the CPU changes the block assignment for partition B.

Figure 34-33. Reassigning Channel Blocks Throughout a McBSP Data Transfer



34.6.5 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (described in Section 34.6.4). If you choose the 8-partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 34-11 and Table 34-12. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 34-11. Receive Channel Assignment and Control With Eight Receive Partitions

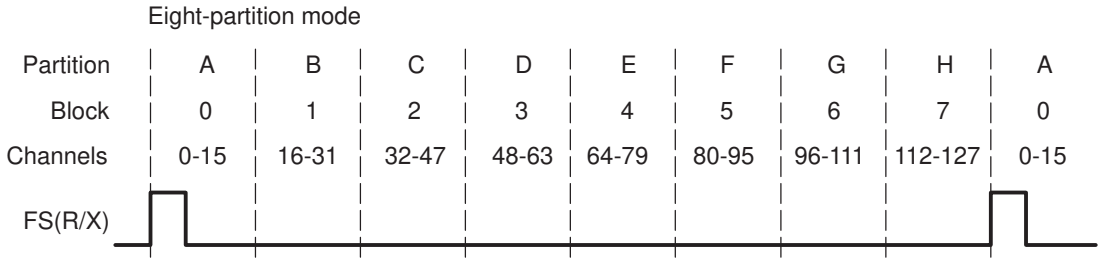
Receive Partition	Assigned Block of Receive Channels	Register Used For Channel Control
A	Block 0: channels 0 through 15	RCERA
B	Block 1: channels 16 through 31	RCERB
C	Block 2: channels 32 through 47	RCERC
D	Block 3: channels 48 through 63	RCERD
E	Block 4: channels 64 through 79	RCERE
F	Block 5: channels 80 through 95	RCERF
G	Block 6: channels 96 through 111	RCERG
H	Block 7: channels 112 through 127	RCERH

Table 34-12. Transmit Channel Assignment and Control When Eight Transmit Partitions Are Used

Transmit Partition	Assigned Block of Transmit Channels	Register Used For Channel Control
A	Block 0: channels 0 through 15	XCERA
B	Block 1: channels 16 through 31	XCERB
C	Block 2: channels 32 through 47	XCERC
D	Block 3: channels 48 through 63	XCERD
E	Block 4: channels 64 through 79	XCERE
F	Block 5: channels 80 through 95	XCERF
G	Block 6: channels 96 through 111	XCERG
H	Block 7: channels 112 through 127	XCERH

Figure 34-34 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 34-34. McBSP Data Transfer in the 8-Partition Mode



34.6.6 Receive Multichannel Selection Mode

The RMCM bit of MCR1 determines whether all channels or only selected channels are enabled for reception. When RMCM = 0, all 128 receive channels are enabled and cannot be disabled. When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit of MCR1.
- If a receive channel is disabled, any bits received in that channel are passed only as far as the receive buffer register(s) (RBR(s)). The receiver does not copy the content of the RBR(s) to the DRR(s), and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated and, if the receiver interrupt mode depends on RRDY (RINTM = 00b), no interrupt is generated.

As an example of how the McBSP behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

1. Accepts bits shifted in from the DR pin in channel 0
2. Ignores bits received in channels 1-14
3. Accepts bits shifted in from the DR pin in channel 15
4. Ignores bits received in channels 16-38
5. Accepts bits shifted in from the DR pin in channel 39

34.6.7 Transmit Multichannel Selection Modes

The XMCM bits of XCR2 determine whether all channels or only selected channels are enabled and unmasked for transmission. More details on enabling and masking are in Section 34.6.7.1. The McBSP has three transmit multichannel selection modes (XMCM = 01b, XMCM = 10b, and XMCM = 11b), which are described in the following table.

Table 34-13. Selecting a Transmit Multichannel Selection Mode With the XMCM Bits

XMCM	Transmit Multichannel Selection Mode
00b	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
01b	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked. The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in XCERs.
10b	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in XCERs.
11b	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in RCERs and XCERs.

As an example of how the McBSP behaves in a transmit multichannel selection mode, suppose that XMCM = 01b (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP:

1. Shifts data to the DX pin in channel 0
2. Places the DX pin in the high impedance state in channels 1-14
3. Shifts data to the DX pin in channel 15
4. Places the DX pin in the high impedance state in channels 16-38
5. Shifts data to the DX pin in channel 39

34.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The following definitions explain the channel control options:

Enabled channel — A channel that can begin transmission by passing data from the data transmit register(s) (DXR(s)) to the transmit shift registers (XSR(s)).

Masked channel — A channel that cannot complete transmission. The DX pin is held in the high impedance state; data cannot be shifted out on the DX pin.

In systems where symmetric transmit and receive provides software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.

Disabled channel — A channel that is not enabled. A disabled channel is also masked.

Because no DXR-to-XSR copy occurs, the XRDY bit of SPCR2 is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 00b in SPCR2), no interrupt is generated.

The XEMPTY bit of SPCR2 is not affected.

Unmasked channel — A channel that is not masked. Data in the XSR(s) is shifted out on the DX pin.

34.6.7.2 Activity on McBSP Pins for Different Values of XMCM

Figure 34-35 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1 = 0000011b: 4 words per frame

- XWDLEN1 = 000b: 8 bits per word
- XMCME = 0: 2-partition mode (only partitions A and B used)

In the case where XMCM = 11b, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

In the figure, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

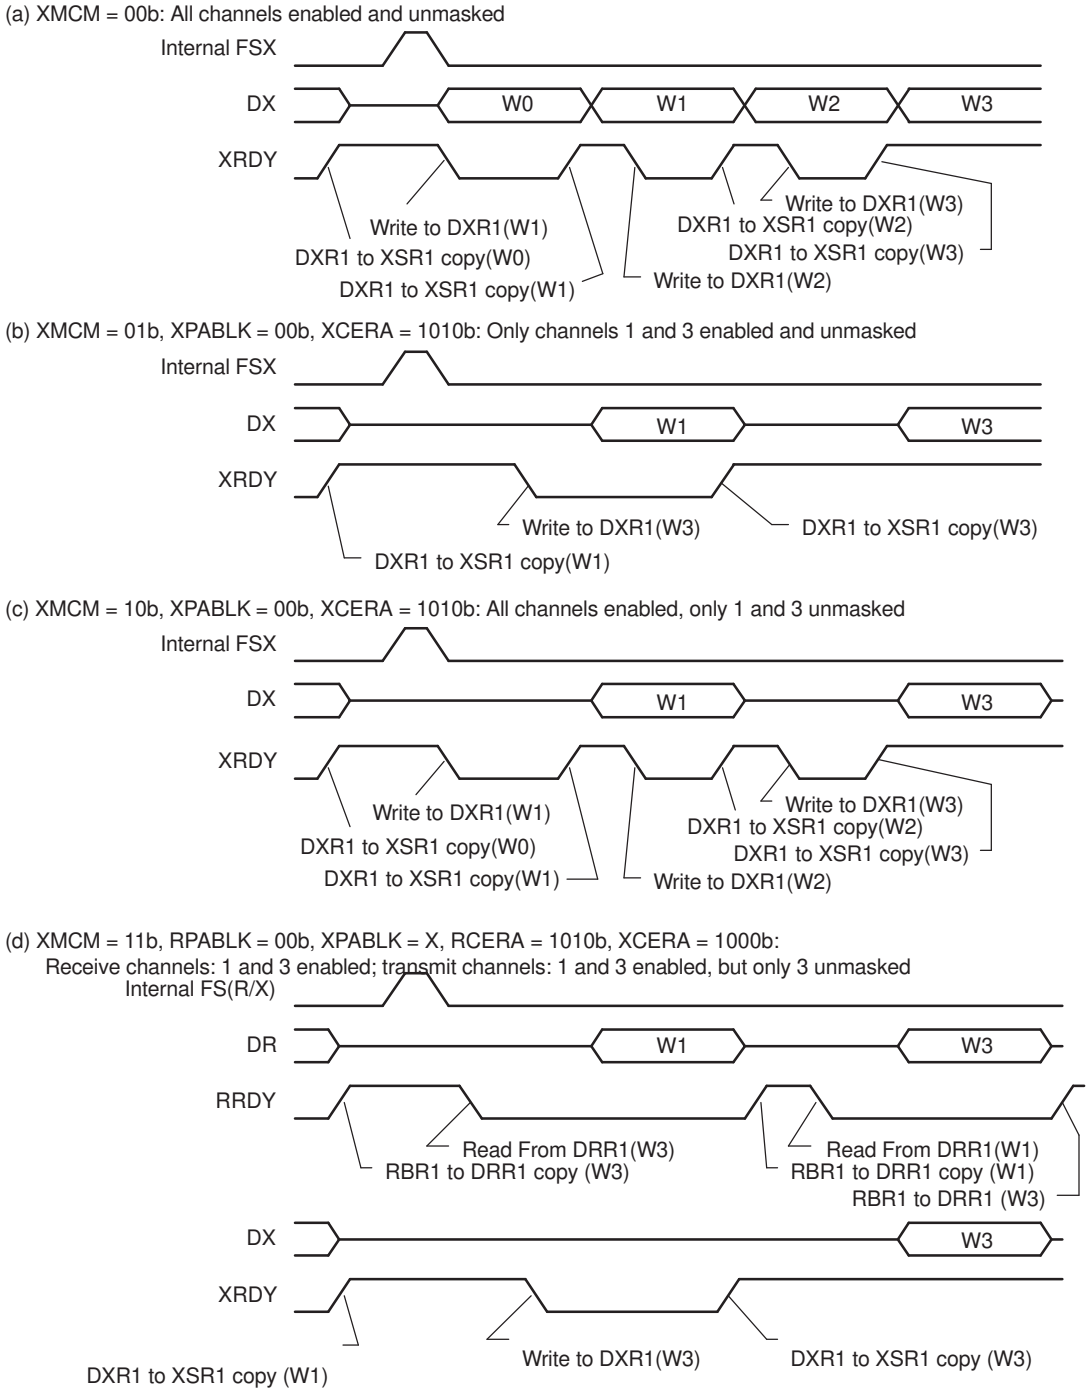
34.6.8 Using Interrupts Between Block Transfers

When a multichannel selection mode is used, an interrupt request can be sent to the CPU at the end of every 16-channel block (at the boundary between partitions and at the end of the frame). In the receive multichannel selection mode, a receive interrupt (RINT) request is generated at the end of each block transfer if RINTM = 01b. In any of the transmit multichannel selection modes, a transmit interrupt (XINT) request is generated at the end of each block transfer if XINTM = 01b. When RINTM/XINTM = 01b, no interrupt is generated unless a multichannel selection mode is on.

These interrupt pulses are active high and last for two CPU clock cycles.

This type of interrupt is especially helpful if you are using the two-partition mode (described in Section 34.6.4) and you want to know when you can assign a different block of channels to partition A or B.

Figure 34-35. Activity on McBSP Pins for the Possible Values of XMCM



34.7 SPI Operation Using the Clock Stop Mode

This chapter explains how to use the McBSP in SPI mode.

34.7.1 SPI Protocol

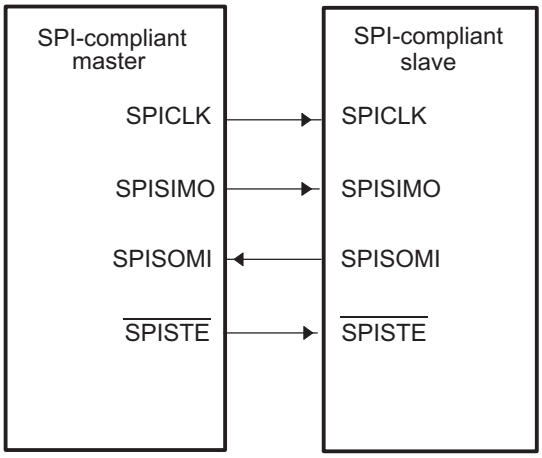
The SPI protocol is a master-slave configuration with one master device and one or more slave devices. The interface consists of the following four signals:

- Serial data input (also referred to as master in/slave out, or SPISOMI)

- Serial data output (also referred to as master out/slave in, or SPISIMO)
- Shift-clock (also referred to as SPICLK)
- Slave-enable signal (also referred to as $\overline{\text{SPISTE}}$)

A typical SPI interface with a single slave device is shown in Figure 34-36.

Figure 34-36. Typical SPI Interface



The master device controls the flow of communication by providing shift-clock and slave-enable signals. The slave-enable signal is an optional active-low signal that enables the serial data input and output of the slave device (device not sending out the clock).

In the absence of a dedicated slave-enable signal, communication between the master and slave is determined by the presence or absence of an active shift-clock. When the McBSP is operating in SPI master mode and the $\overline{\text{SPISTE}}$ signal is not used by the slave SPI port, the slave device must remain enabled at all times, and multiple slaves cannot be used.

34.7.2 Clock Stop Mode

The clock stop mode of the McBSP provides compatibility with the SPI protocol. When the McBSP is configured in clock stop mode, the transmitter and receiver are internally synchronized so that the McBSP functions as an SPI master or slave device. The transmit clock signal (CLKX) corresponds to the serial clock signal (SPICLK) of the SPI protocol, while the transmit frame-synchronization signal (FSX) is used as the slave-enable signal ($\overline{\text{SPISTE}}$).

The receive clock signal (MCLKR) and receive frame-synchronization signal (FSR) are not used in the clock stop mode because these signals are internally connected to their transmit counterparts, CLKX and FSX.

34.7.3 Enable and Configure the Clock Stop Mode

The bits required to configure the McBSP as an SPI device are introduced in Table 34-14. Table 34-15 shows how the various combinations of the CLKSTP bit and the polarity bits CLKXP and CLKRP create four possible clock stop mode configurations. The timing diagrams in Section 34.7.4 show the effects of CLKSTP, CLKXP, and CLKRP.

Table 34-14. Bits Used to Enable and Configure the Clock Stop Mode

Bit Field	Description
CLKSTP bits of SPCR1	Use these bits to enable the clock stop mode and to select one of two timing variations. (See also Table 34-15.)
CLKXP bit of PCR	This bit determines the polarity of the CLKX signal. (See also Table 34-15.)
CLKRP bit of PCR	This bit determines the polarity of the MCLKR signal. (See also Table 34-15.)
CLKXM bit of PCR	This bit determines whether CLKX is an input signal (McBSP as slave) or an output signal (McBSP as master).

Table 34-14. Bits Used to Enable and Configure the Clock Stop Mode (continued)

Bit Field	Description
XPHASE bit of XCR2	You must use a single-phase transmit frame (XPHASE = 0).
RPHASE bit of RCR2	You must use a single-phase receive frame (RPHASE = 0).
XFRLEN1 bits of XCR1	You must use a transmit frame length of 1 serial word (XFRLEN1 = 0).
RFRLEN1 bits of RCR1	You must use a receive frame length of 1 serial word (RFRLEN1 = 0).
XWDLEN1 bits of XCR1	The XWDLEN1 bits determine the transmit packet length. XWDLEN1 must be equal to RWDLEN1 because in the clock stop mode. The McBSP transmit and receive circuits are synchronized to a single clock.
RWDLEN1 bits of RCR1	The RWDLEN1 bits determine the receive packet length. RWDLEN1 must be equal to XWDLEN1 because in the clock stop mode. The McBSP transmit and receive circuits are synchronized to a single clock.

Table 34-15. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme

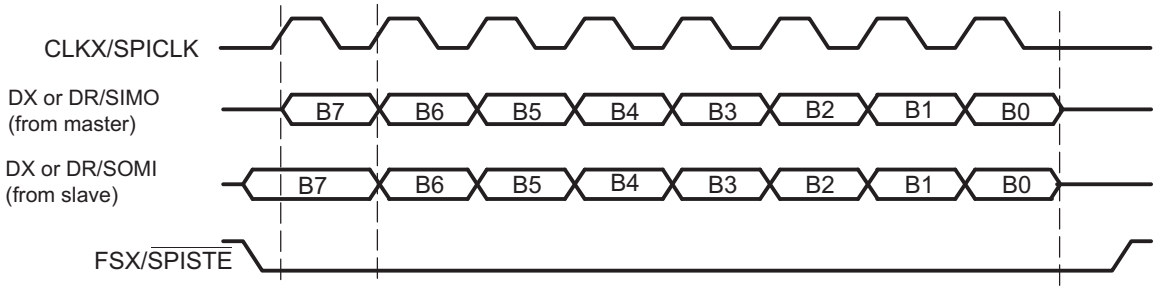
Bit Settings	Clock Scheme
CLKSTP = 00b or 01b CLKXP = 0 or 1 CLKRP = 0 or 1	Clock stop mode disabled. Clock enabled for non-SPI mode.
CLKSTP = 10b CLKXP = 0 CLKRP = 0	Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR.
CLKSTP = 11b CLKXP = 0 CLKRP = 1	Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 10b CLKXP = 1 CLKRP = 0	High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 11b CLKXP = 1 CLKRP = 1	High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR.

34.7.4 Clock Stop Mode Timing Diagrams

The timing diagrams for the four possible clock stop mode configurations are shown here. Notice that the frame-synchronization signal used in clock stop mode is active throughout the entire transmission as a slave-enable signal. Although the timing diagrams show 8-bit transfers, the packet length can be set to 8, 12, 16, 20, 24, or 32 bits per packet. The receive packet length is selected with the RWDLEN1 bits of RCR1, and the transmit packet length is selected with the XWDLEN1 bits of XCR1. For clock stop mode, the values of RWDLEN1 and XWDLEN1 must be the same because the McBSP transmit and receive circuits are synchronized to a single clock.

NOTE: Even if multiple words are consecutively transferred, the CLKX signal is always stopped and the FSX signal returns to the inactive state after a packet transfer. When consecutive packet transfers are performed, this leads to a minimum idle time of two bit-periods between each packet transfer.

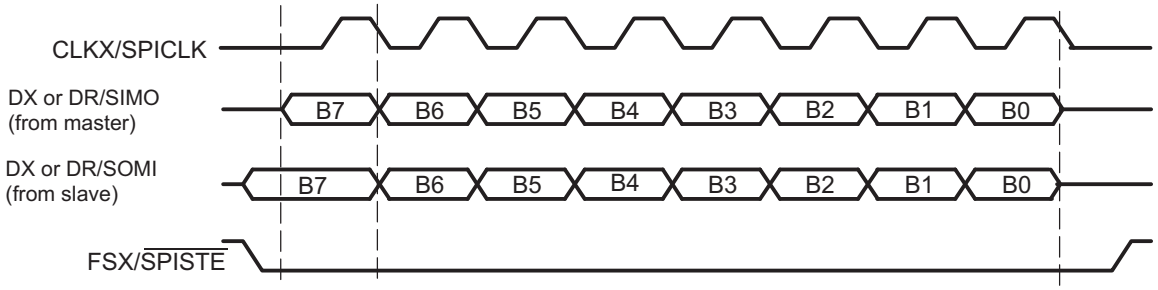
Figure 34-37. SPI Transfer With CLKSTP = 10b (No Clock Delay), CLKXP = 0, and CLKRP = 0



A If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.

B If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

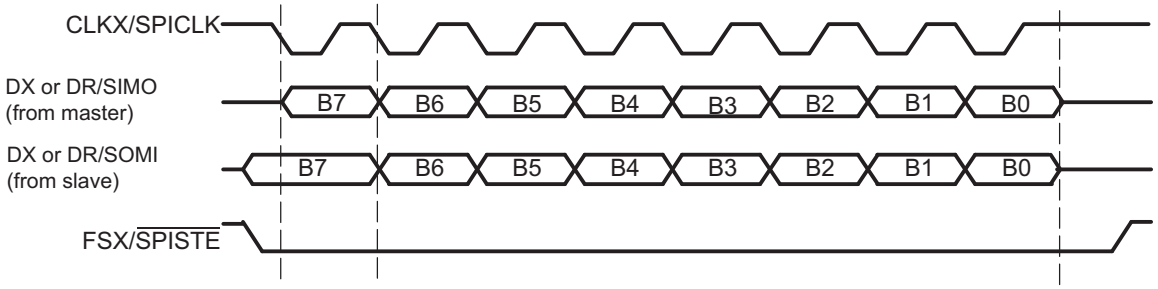
Figure 34-38. SPI Transfer With CLKSTP = 11b (Clock Delay), CLKXP = 0, CLKRP = 1



A If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.

B If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

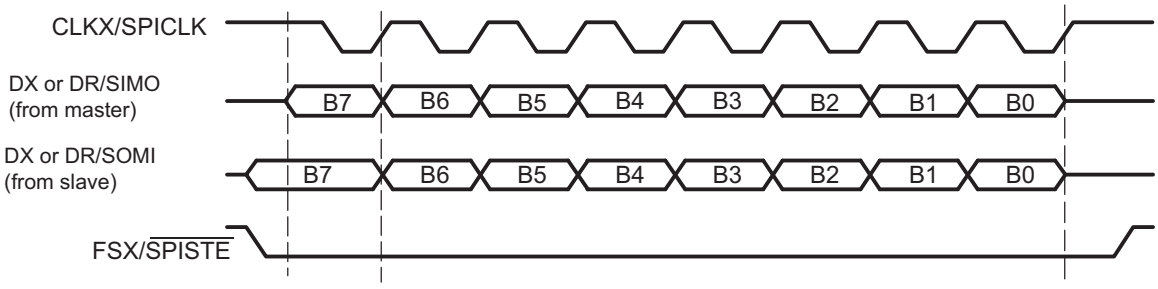
Figure 34-39. SPI Transfer With CLKSTP = 10b (No Clock Delay), CLKXP = 1, and CLKRP = 0



A If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.

B If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

Figure 34-40. SPI Transfer With CLKSTP = 11b (Clock Delay), CLKXP = 1, CLKRP = 1



A If the McBSP is the SPI master (CLKXM = 1), SIMO=DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.

B If the McBSP is the SPI master (CLKXM = 1), SOMI=DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

34.7.5 Procedure for Configuring a McBSP for SPI Operation

To configure the McBSP for SPI master or slave operation:

Step 1. Place the transmitter and receiver in reset.

Clear the transmitter reset bit (XRST = 0) in SPCR2 to reset the transmitter. Clear the receiver reset bit (RRST = 0) in SPCR1 to reset the receiver.

Step 2. Place the sample rate generator in reset.

Clear the sample rate generator reset bit (GRST = 0) in SPCR2 to reset the sample rate generator.

Step 3. Program registers that affect SPI operation.

Program the appropriate McBSP registers to configure the McBSP for proper operation as an SPI master or an SPI slave. For a list of important bits settings, see one of the following topics:

- *McBSP as the SPI Master* (Section 34.7.6)
- *McBSP as an SPI Slave* (Section 34.7.7)

Step 4. Enable the sample rate generator.

To release the sample rate generator from reset, set the sample rate generator reset bit (GRST = 1) in SPCR2.

Make sure that during the write to SPCR2, you only modify GRST. Otherwise, you modify the McBSP configuration you selected in the previous step.

Step 5. Enable the transmitter and receiver.

After the sample rate generator is released from reset, wait two sample rate generator clock periods for the McBSP logic to stabilize.

If the CPU services the McBSP transmit and receive buffers, then you can immediately enable the transmitter (XRST = 1 in SPCR2) and enable the receiver (RRST = 1 in SPCR1).

If the DMA controller services the McBSP transmit and receive buffers, then you must first configure the DMA controller (this includes enabling the channels that service the McBSP buffers). When the DMA controller is ready, make XRST = 1 and RRST = 1.

In either case, make sure you only change XRST and RRST when you write to SPCR2 and SPCR1. Otherwise, you modify the bit settings you selected earlier in this procedure.

After the transmitter and receiver are released from reset, wait two sample rate generator clock periods for the McBSP logic to stabilize.

Step 6. If necessary, enable the frame-synchronization logic of the sample rate generator.

After the required data acquisition setup is done (DXR[1,2] is loaded with data), set FRST = 1 if an internally generated frame-synchronization pulse is required (that is, if the McBSP is the SPI master).

34.7.6 McBSP as the SPI Master

An SPI interface with the McBSP used as the master is shown in Figure 34-41. When the McBSP is configured as a master, the transmit output signal (DX) is used as the SPISIMO signal of the SPI protocol and the receive input signal (DR) is used as the SPISOMI signal.

The register bit values required to configure the McBSP as a master are listed in Table 34-16. After the table are more details about the configuration requirements.

Figure 34-41. SPI Interface with McBSP Used as Master

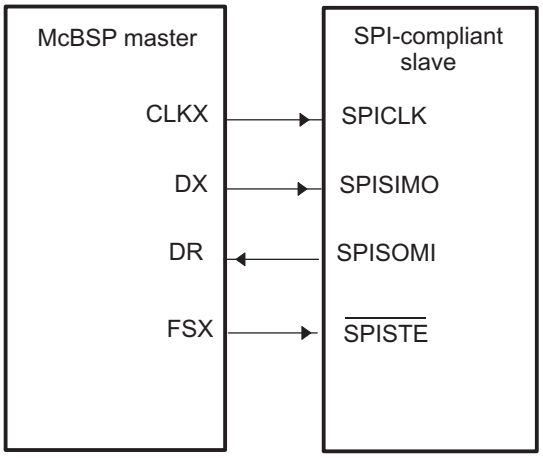


Table 34-16. Bit Values Required to Configure the McBSP as an SPI Master

Required Bit Setting	Description
CLKSTP = 10b or 11b	The clock stop mode (without or with a clock delay) is selected.
CLKXP = 0 or 1	The polarity of CLKX as seen on the MCLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1).
CLKRP = 0 or 1	The polarity of MCLKR as seen on the MCLKR pin is positive (CLKRP = 0) or negative (CLKRP = 1).
CLKXM = 1	The MCLKX pin is an output pin driven by the internal sample rate generator. Because CLKSTP is equal to 10b or 11b, MCLKR is driven internally by CLKX.
SCLKME = 0	The clock generated by the sample rate generator (CLKG) is derived from the CPU clock.
CLKSM = 1	
CLKGDV is a value from 1 to 255	CLKGDV defines the divide down value for CLKG.
FSXM = 1	The FSX pin is an output pin driven according to the FSGM bit.
FSGM = 0	The transmitter drives a frame-synchronization pulse on the FSX pin every time data is transferred from DXR1 to XSR1.
FSXP = 1	The FSX pin is active low.
XDATDLY = 01b	This setting provides the correct setup time on the FSX signal.
RDATDLY = 01b	

When the McBSP functions as the SPI master, it controls the transmission of data by producing the serial clock signal. The clock signal on the MCLKX pin is enabled only during packet transfers. When packets are not being transferred, the MCLKX pin remains high or low depending on the polarity used.

For SPI master operation, the MCLKX pin must be configured as an output. The sample rate generator is then used to derive the CLKX signal from the CPU clock. The clock stop mode internally connects the MCLKX pin to the MCLKR signal so that no external signal connection is required on the MCLKR pin and both the transmit and receive circuits are clocked by the master clock (CLKX).

The data delay parameters of the McBSP (XDATDLY and RDATDLY) must be set to 1 for proper SPI master operation. A data delay value of 0 or 2 is undefined in the clock stop mode.

The McBSP can also provide a slave-enable signal (SS_) on the FSX pin. If a slave-enable signal is required, the FSX pin must be configured as an output and the transmitter must be configured so that a frame-synchronization pulse is generated automatically each time a packet is transmitted (FSGM = 0). The polarity of the FSX pin is programmable high or low; however, in most cases the pin must be configured active low.

When the McBSP is configured as described for SPI-master operation, the bit fields for frame-synchronization pulse width (FWID) and frame-synchronization period (FPER) are overridden, and custom frame-synchronization waveforms are not allowed. To see the resulting waveform produced on the FSX pin, see the timing diagrams in Section 34.7.4. The signal becomes active before the first bit of a packet transfer, and remains active until the last bit of the packet is transferred. After the packet transfer is complete, the FSX signal returns to the inactive state.

34.7.7 McBSP as an SPI Slave

An SPI interface with the McBSP used as a slave is shown in Figure 34-42. When the McBSP is configured as a slave, DX is used as the SPISOMI signal and DR is used as the SPISIMO signal.

The register bit values required to configure the McBSP as a slave are listed in Table 34-17. Following the table are more details about configuration requirements.

Figure 34-42. SPI Interface With McBSP Used as Slave

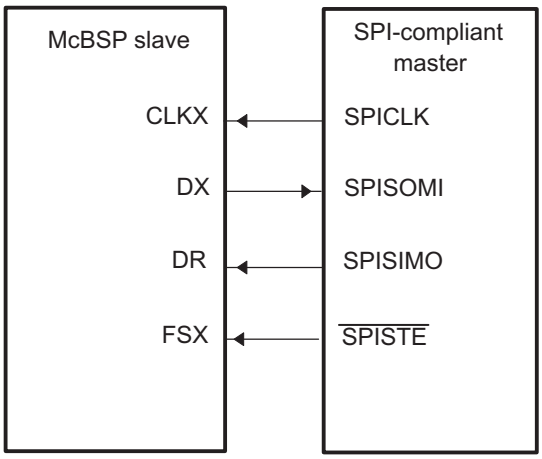

Table 34-17. Bit Values Required to Configure the McBSP as an SPI Slave

Required Bit Setting	Description
CLKSTP = 10b or 11b	The clock stop mode (without or with a clock delay) is selected.
CLKXP = 0 or 1	The polarity of CLKX as seen on the MCLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1).
CLKRP = 0 or 1	The polarity of MCLKR as seen on the MCLKR pin is positive (CLKRP = 0) or negative (CLKRP = 1).
CLKXM = 0	The MCLKX pin is an input pin, so that it can be driven by the SPI master. Because CLKSTP = 10b or 11b, MCLKR is driven internally by CLKX.
SCLKME = 0 CLKSM = 1	The clock generated by the sample rate generator (CLKG) is derived from the CPU clock. (The sample rate generator is used to synchronize the McBSP logic with the externally-generated master clock.)
CLKGDV = 1	The sample rate generator divides the CPU clock before generating CLKG.
FSXM = 0	The FSX pin is an input pin, so that it can be driven by the SPI master.
FSXP = 1	The FSX pin is active low.
XDATDLY = 00b	These bits must be 0s for SPI slave operation.
RDATDLY = 00b	

When the McBSP is used as an SPI slave, the master clock and slave-enable signals are generated externally by a master device. Accordingly, the CLKX and FSX pins must be configured as inputs. The MCLKX pin is internally connected to the MCLKR signal, so that both the transmit and receive circuits of the McBSP are clocked by the external master clock. The FSX pin is also internally connected to the FSR signal, and no external signal connections are required on the MCLKR and FSR pins.

Although the CLKX signal is generated externally by the master and is asynchronous to the McBSP, the sample rate generator of the McBSP must be enabled for proper SPI slave operation. The sample rate generator must be programmed to its maximum rate of half the CPU clock rate. The internal sample rate clock is then used to synchronize the McBSP logic to the external master clock and slave-enable signals.

The McBSP requires an active edge of the slave-enable signal on the FSX input for each transfer. This means that the master device must assert the slave-enable signal at the beginning of each transfer, and deassert the signal after the completion of each packet transfer; the slave-enable signal cannot remain active between transfers. Unlike the standard SPI, this pin cannot be tied low all the time.

The data delay parameters of the McBSP must be set to 0 for proper SPI slave operation. A value of 1 or 2 is undefined in the clock stop mode.

34.8 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP/receiver in reset (see Section 34.8.2).
2. Program McBSP registers for the desired receiver operation (see Section 34.8.1).
3. Take the receiver out of reset (see Section 34.8.2).

34.8.1 Programming the McBSP Registers for the Desired Receiver Operation

The following is a list of important tasks to be performed when you are configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

- Global behavior:
  - Set the receiver pins to operate as McBSP pins.
  - Enable/disable the digital loopback mode.
  - Enable/disable the clock stop mode.
  - Enable/disable the receive multichannel selection mode.
- Data behavior:
  - Choose 1 or 2 phases for the receive frame.
  - Set the receive word length(s).
  - Set the receive frame length.
  - Enable/disable the receive frame-synchronization ignore function.
  - Set the receive companding mode.
  - Set the receive data delay.
  - Set the receive sign-extension and justification mode.
  - Set the receive interrupt mode.
- Frame-synchronization behavior:
  - Set the receive frame-synchronization mode.
  - Set the receive frame-synchronization polarity.
  - Set the sample rate generator (SRG) frame-synchronization period and pulse width.
- Clock behavior:
  - Set the receive clock mode.
  - Set the receive clock polarity.
  - Set the SRG clock divide-down value.
  - Set the SRG clock synchronization mode.
  - Set the SRG clock mode (choose an input clock).
  - Set the SRG input clock polarity.

34.8.2 Resetting and Enabling the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset). Table 34-18 describes the bits used for both of these steps.

Table 34-18. Register Bits Used to Reset or Enable the McBSP Receiver Field Descriptions

Register	Bit	Field	Value	Description
SPCR2	7	FRST		Frame-synchronization logic reset
			0	Frame-synchronization logic is reset. The sample rate generator does not generate frame-synchronization signal FSG, even if GRST = 1.
			1	If GRST = 1, frame-synchronization signal FSG is generated after (FPER + 1) number of CLKG clock cycles; all frame counters are loaded with their programmed values.
SPCR2	6	GRST		Sample rate generator reset
			0	Sample rate generator is reset. If GRST = 0 due to a DSP reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive).
			1	Sample rate generator is enabled. CLKG is driven according to the configuration programmed in the sample rate generator registers (SRGR[1,2]). If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers.
SPCR1	0	RRST		Receiver reset
			0	The serial port receiver is disabled and in the reset state.
			1	The serial port receiver is enabled.

34.8.2.1 Reset Considerations

The serial port can be reset in the following two ways:

1. The DSP reset ($\overline{\text{XRS}}$ signal driven low) places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed ($\overline{\text{XRS}}$ signal released), GRST = FRST = RRST = XRST = 0 keep the entire serial port in the reset state, provided the McBSP clock is turned on.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the serial port control registers. The sample rate generator can be reset directly using the GRST bit in SPCR2.

Table 34-19 shows the state of McBSP pins when the serial port is reset due to a device reset and a direct receiver/transmitter reset.

For more details about McBSP reset conditions and effects, see Section 34.10.2.

Table 34-19. Reset State of Each McBSP Pin

Pin	Possible State(s)	State Forced By Device Reset	State Forced By Receiver Reset (RRST = 0 and GRST = 1)
MDRx	I	GPIO Input	Input
MCLKRx	I/O/Z	GPIO Input	Known state if input; MCLKR running if output
MFSRx	I/O/Z	GPIO Input	Known state if input; FSRP inactive state if output
			Transmitter reset (XRST = 0 and GRST = 1)
MDXx	O/Z	GPIO Input	Low impedance after transmit bit clock provided
MCLKXx	I/O/Z	GPIO Input	Known state if input; CLKX running if output
MFSXx	I/O/Z	GPIO Input	Known state if input; FSXP inactive state if output

34.8.3 Set the Receiver Pins to Operate as McBSP Pins

To configure a pin for its McBSP function , you should configure the bits of the GPxMUXn register appropriately. In addition to this, bits 12 and 13 of the PCR register must be set to 0. These bits are defined as reserved.

34.8.4 Digital Loopback Mode

The DLB bit determines whether the digital loopback mode is on. DLB is described in Table 34-20.

Table 34-20. Register Bit Used to Enable/Disable the Digital Loopback Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	15	DLB	Digital loopback mode		R/W	0
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled.		

34.8.4.1 Digital Loopback Mode

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals, as shown in Table 34-21. This mode allows testing of serial port code with a single DSP device; the McBSP receives the data it transmits.

Table 34-21. Receive Signals Connected to Transmit Signals in Digital Loopback Mode

This Receive Signal	Is Fed Internally by This Transmit Signal
MDR (receive data)	MDX (transmit data)
MFSR (receive frame synchronization)	MFSX (transmit frame synchronization)
MCLKR (receive clock)	MCLKX (transmit clock)

34.8.5 Clock Stop Mode

The CLKSTP bits determine whether the clock stop mode is on. CLKSTP is described in Table 34-22.

Table 34-22. Register Bits Used to Enable/Disable the Clock Stop Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode		
			CLKSTP = 10b	Clock stop mode enabled, without clock delay		
			CLKSTP = 11b	Clock stop mode enabled, with clock delay		

34.8.5.1 Clock Stop Mode

The clock stop mode supports the SPI master-slave protocol. If you do not plan to use the SPI protocol, you can clear CLKSTP to disable the clock stop mode.

In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). The CLKXP bit determines whether the starting edge of the clock on the MCLKX pin is rising or falling. The CLKRP bit determines whether receive data is sampled on the rising or falling edge of the clock shown on the MCLKR pin.

Table 34-23 summarizes the impact of CLKSTP, CLKXP, and CLKRP on serial port operation. In the clock stop mode, the receive clock is tied internally to the transmit clock, and the receive frame-synchronization signal is tied internally to the transmit frame-synchronization signal.

Table 34-23. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme

Bit Settings	Clock Scheme
CLKSTP = 00b or 01b CLKXP = 0 or 1 CLKRP = 0 or 1	Clock stop mode disabled. Clock enabled for non-SPI mode.
CLKSTP = 10b CLKXP = 0 CLKRP = 0	Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR.
CLKSTP = 11b CLKXP = 0 CLKRP = 1	Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 10b CLKXP = 1 CLKRP = 0	High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 11b CLKXP = 1 CLKRP = 1	High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR.

34.8.6 Receive Multichannel Selection Mode

The RMCM bit determines whether the receive multichannel selection mode is on. RMCM is described in Table 34-24. For more details, see Section 34.6.6.

Table 34-24. Register Bit Used to Enable/Disable the Receive Multichannel Selection Mode

Register	Bit	Name	Function		Type	Reset Value
MCR1	0	RMCM	Receive multichannel selection mode		R/W	0
			RMCM = 0	The mode is disabled. All 128 channels are enabled.		
			RMCM = 1	The mode is enabled. Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit.		

34.8.7 Receive Frame Phases

The RPHASE bit (see Table 34-25) determines whether the receive data frame has one or two phases.

Table 34-25. Register Bit Used to Choose One or Two Phases for the Receive Frame

Register	Bit	Name	Function		Type	Reset Value
RCR2	15	RPHASE	Receive phase number		R/W	0
			Specifies whether the receive frame has 1 or 2 phases.			
			RPHASE = 0	Single-phase frame		
			RPHASE = 1	Dual-phase frame		

34.8.8 Receive Word Length(s)

The RWDLEN1 and RWDLEN2 bit fields (see Table 34-26) determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

Table 34-26. Register Bits Used to Set the Receive Word Length(s)

Register	Bit	Name	Function		Type	Reset Value
RCR1	7-5	RWDLEN1	Receive word length 1		R/W	000
			Specifies the length of every serial word in phase 1 of the receive frame.			
			RWDLEN1 = 000	8 bits		
			RWDLEN1 = 001	12 bits		
			RWDLEN1 = 010	16 bits		
			RWDLEN1 = 011	20 bits		
			RWDLEN1 = 100	24 bits		
			RWDLEN1 = 101	32 bits		
			RWDLEN1 = 11X	Reserved		
RCR2	7-5	RWDLEN2	Receive word length 2		R/W	000
			If a dual-phase frame is selected, RWDLEN2 specifies the length of every serial word in phase 2 of the frame.			
			RWDLEN2 = 000	8 bits		
			RWDLEN2 = 001	12 bits		
			RWDLEN2 = 010	16 bits		
			RWDLEN2 = 011	20 bits		
			RWDLEN2 = 100	24 bits		
			RWDLEN2 = 101	32 bits		
			RWDLEN2 = 11X	Reserved		

34.8.8.1 Word Length Bits

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame and RWDLEN2 determines the word length in phase 2 of the frame.

34.8.9 Receive Frame Length

The RFRLEN1 and RFRLEN2 bit fields (see Table 34-27) determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

Table 34-27. Register Bits Used to Set the Receive Frame Length

Register	Bit	Name	Function		Type	Reset Value
RCR1	14-8	RFRLEN1	Receive frame length 1		R/W	000 0000
			(RFRLEN1 + 1) is the number of serial words in phase 1 of the receive frame.			
			RFRLEN1 = 000 0000	1 word in phase 1		
			RFRLEN1 = 000 0001	2 words in phase 1		
			|	|		
			|	|		
			RFRLEN1 = 111 1111	128 words in phase 1		

Table 34-27. Register Bits Used to Set the Receive Frame Length (continued)

Register	Bit	Name	Function		Type	Reset Value
RCR2	14-8	RFRLEN2	Receive frame length 2		R/W	000 0000
			If a dual-phase frame is selected, (RFRLEN2 + 1) is the number of serial words in phase 2 of the receive frame.			
			RFRLEN2 = 000 0000	1 word in phase 2		
			RFRLEN2 = 000 0001	2 words in phase 2		
			|	|		
			|	|		
			RFRLEN2 = 111 1111	128 words in phase 2		

34.8.9.1 Selected Frame Length

The receive frame length is the number of serial words in the receive frame. Each frame can have one or two phases, depending on value that you load into the RPHASE bit.

If a single-phase frame is selected (RPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (RPHASE = 1), the frame length is the length of phase 1 plus the length of phase 2.

The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 34-28 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into RFRLEN1.

Table 34-28. How to Calculate the Length of the Receive Frame

RPHASE	RFRLEN1	RFRLEN2	Frame Length
0	0 ≤ RFRLEN1 ≤ 127	Don't care	(RFRLEN1 + 1) words
1	0 ≤ RFRLEN1 ≤ 127	0 ≤ RFRLEN2 ≤ 127	(RFRLEN1 + 1) + (RFRLEN2 + 1) words

34.8.10 Receive Frame-Synchronization Ignore Function

The RFIG bit (see Table 34-29) controls the receive frame-synchronization ignore function.

Table 34-29. Register Bit Used to Enable/Disable the Receive Frame-Synchronization Ignore Function

Register	Bit	Name	Function		Type	Reset Value
RCR2	2	RFIG	Receive frame-synchronization ignore		R/W	0
			RFIG = 0	An unexpected receive frame-synchronization pulse causes the McBSP to restart the frame transfer.		
			RFIG = 1	The McBSP ignores unexpected receive frame-synchronization pulses.		

34.8.10.1 Unexpected Frame-Synchronization Pulses and the Frame-Synchronization Ignore Function

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse.

When RFIG = 1, reception continues, ignoring the unexpected frame-synchronization pulses.

When RFIG = 0, an unexpected FSR pulse causes the McBSP to discard the contents of RSR[1,2] in favor of the new incoming data. Therefore, if RFIG = 0 and an unexpected frame-synchronization pulse occurs, the serial port:

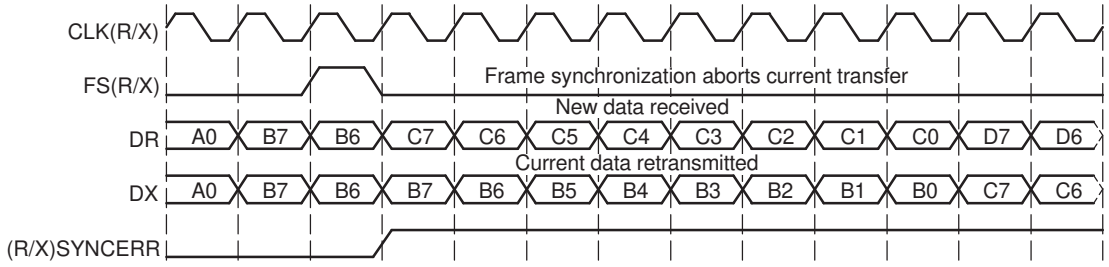
1. Aborts the current data transfer
2. Sets RSYNCERR in SPCR1 to 1
3. Begins the transfer of a new data word

For more details about the frame-synchronization error condition, see Section 34.5.3.

34.8.10.2 Examples of Effects of RFIG

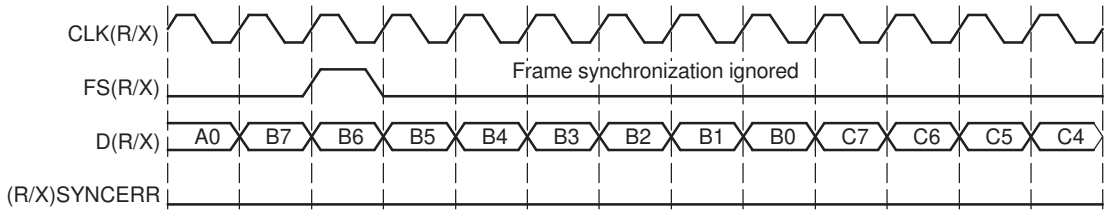
Figure 34-43 shows an example in which word B is interrupted by an unexpected frame-synchronization pulse when (R/X)FIG = 0. In the case of reception, the reception of B is aborted (B is lost), and a new data word C in this example) is received after the appropriate data delay. This condition is a receive synchronization error, which sets the RSYNCERR bit.

Figure 34-43. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 0



In contrast with Figure 34-43, Figure 34-44 shows McBSP operation when unexpected frame-synchronization signals are ignored (when (R/X)FIG = 1). Here, the transfer of word B is not affected by an unexpected pulse.

Figure 34-44. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 1



34.8.11 Receive Companding Mode

The RCOMPAND bits (see Table 34-30) determine whether companding or another data transfer option is chosen for McBSP reception.

Table 34-30. Register Bits Used to Set the Receive Companding Mode

Register	Bit	Name	Function		Type	Reset Value
RCR2	4-3	RCOMPAND	Receive companding mode		R/W	00
			Modes other than 00b are enabled only when the appropriate RWDLEN is 000b, indicating 8-bit data.			
			RCOMPAND = 00	No companding, any size data, MSB received first		
			RCOMPAND = 01	No companding, 8-bit data, LSB received first (for details, see Section 34.8.11.4).		
			RCOMPAND = 10	μ-law companding, 8-bit data, MSB received first		
			RCOMPAND = 11	A-law companding, 8-bit data, MSB received first		

34.8.11.1 Companding

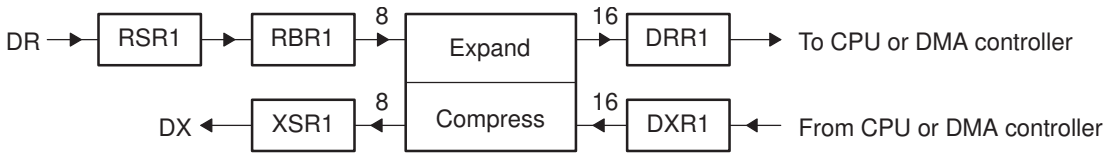
Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 34-45 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to 2's-complement format.

Figure 34-45. Companding Processes for Reception and for Transmission



34.8.11.2 Format of Expanded Data

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The RJUST bit of SPCR1 is ignored when companding is used.

34.8.11.3 Companding Internal Data

If the McBSP is otherwise unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. See Section 34.3.2.2.

34.8.11.4 Option to Receive LSB First

Normally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits and LSB-first ordering is done.

34.8.12 Receive Data Delay

The RDATDLY bits (see Table 34-31) determine the length of the data delay for the receive frame.

Table 34-31. Register Bits Used to Set the Receive Data Delay

Register	Bit	Name	Function		Type	Reset Value
RCR2	1-0	RDATDLY	Receive data delay		R/W	00
			RDATDLY = 00	0-bit data delay		
			RDATDLY = 01	1-bit data delay		
			RDATDLY = 10	2-bit data delay		
			RDATDLY = 11	Reserved		

34.8.12.1 Data Delay

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

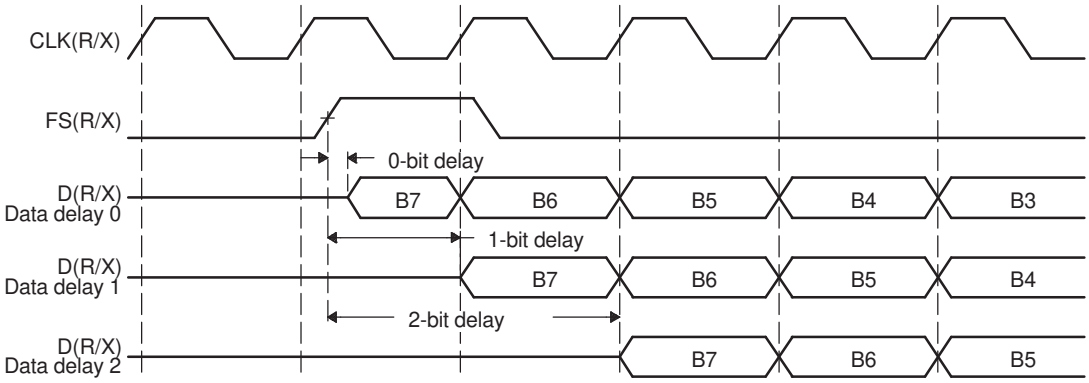
RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY = 00b-10b), as described in Table 34-31 and shown in Figure 34-46. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

34.8.12.2 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of MCLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on DX. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the DX pin.

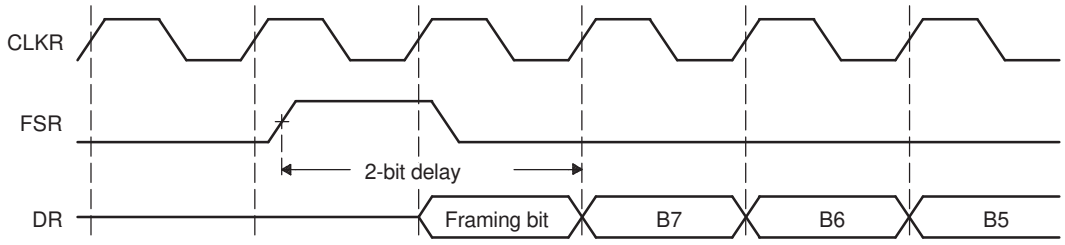
Figure 34-46. Range of Programmable Data Delay



34.8.12.3 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 34-47. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 34-47. 2-Bit Data Delay Used to Skip a Framing Bit



34.8.13 Receive Sign-Extension and Justification Mode

The RJUST bits (see Table 34-32) determine whether data received by the McBSP is sign-extended and how it is justified.

Table 34-32. Register Bits Used to Set the Receive Sign-Extension and Justification Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	14-13	RJUST	Receive sign-extension and justification mode		R/W	00
			RJUST = 00	Right justify data and zero fill MSBs in DRR[1,2]		
			RJUST = 01	Right justify data and sign extend it into the MSBs in DRR[1,2]		
			RJUST = 10	Left justify data and zero fill LSBs in DRR[1,2]		
			RJUST = 11	Reserved		

34.8.13.1 Sign-Extension and the Justification

RJUST in SPCR1 selects whether data in RBR[1,2] is right- or left-justified (with respect to the MSB) in DRR[1,2] and whether unused bits in DRR[1,2] are filled with zeros or with sign bits.

Table 34-33 and Table 34-34 show the effects of various RJUST values. The first table shows the effect on an example 12-bit receive-data value ABCh. The second table shows the effect on an example 20-bit receive-data value ABCDEh.

Table 34-33. Example: Use of RJUST Field With 12-Bit Data Value ABCh

RJUST	Justification	Extension	Value in DRR2	Value in DRR1
00b	Right	Zero fill MSBs	0000h	0ABCh
01b	Right	Sign extend data into MSBs	FFFFh	FABCh
10b	Left	Zero fill LSBs	0000h	ABC0h
11b	Reserved	Reserved	Reserved	Reserved

Table 34-34. Example: Use of RJUST Field With 20-Bit Data Value ABCDEh

RJUST	Justification	Extension	Value in DRR2	Value in DRR1
00b	Right	Zero fill MSBs	000Ah	BCDEh
01b	Right	Sign extend data into MSBs	FFFAh	BCDEh
10b	Left	Zero fill LSBs	ABCDh	E000h

34.8.14 Receive Interrupt Mode

The RINTM bits (see Table 34-35) determine which event generates a receive interrupt request to the CPU.

The receive interrupt (RINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt. The options are set by the receive interrupt mode bits, RINTM, in SPCR1.

Table 34-35. Register Bits Used to Set the Receive Interrupt Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	5-4	RINTM	Receive interrupt mode		R/W	00
			RINTM = 00	RINT generated when RRDY changes from 0 to 1. Interrupt on every serial word by tracking the RRDY bit in SPCR1. Regardless of the value of RINTM, RRDY can be read to detect the RRDY = 1 condition.		
			RINTM = 01	RINT generated by an end-of-block or end-of-frame condition in the receive multichannel selection mode. In the multichannel selection mode, interrupt after every 16-channel block boundary has been crossed within a frame and at the end of the frame. For details, see Section 34.6.8. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.		
			RINTM = 10	RINT generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending it to the CPU via RINT.		
			RINTM = 11	RINT generated when RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see Section 34.5.3.		

34.8.15 Receive Frame-Synchronization Mode

The bits described in Table 34-36 determine the source for receive frame synchronization and the function of the FSR pin.

34.8.15.1 Receive Frame-Synchronization Modes

Table 34-37 shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the FSR pin. The polarity of the signal on the FSR pin is determined by the FSRP bit.

In digital loopback mode (DLB = 1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the clock stop mode, the internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

Table 34-36. Register Bits Used to Set the Receive Frame Synchronization Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	10	FSRM	Receive frame-synchronization mode		R/W	0
			FSRM = 0	Receive frame synchronization is supplied by an external source via the FSR pin.		
			FSRM = 1	Receive frame synchronization is supplied by the sample rate generator. FSR is an output pin reflecting internal FSR, except when GSYNC = 1 in SRGR2.		

Table 34-36. Register Bits Used to Set the Receive Frame Synchronization Mode (continued)

Register	Bit	Name	Function		Type	Reset Value
SRGR2	15	GSYNC	Sample rate generator clock synchronization mode		R/W	0
			If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the FSR pin.			
			GSYNC = 0	No clock synchronization is used: CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles.		
			GSYNC = 1	Clock synchronization is used. When a pulse is detected on the FSR pin: • CLKG is adjusted as necessary so that it is synchronized with the input clock on the MCLKR pin. • FSG pulses FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored. For more details, see Section 34.4.3.		
SPCR1	15	DLB	Digital loopback mode		R/W	0
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled. The receive signals, including the receive frame-synchronization signal, are connected internally through multiplexers to the corresponding transmit signals.		
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode.		
			CLKSTP = 10b	Clock stop mode enabled without clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		
			CLKSTP = 11b	Clock stop mode enabled with clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		

Table 34-37. Select Sources to Provide the Receive Frame-Synchronization Signal and the Effect on the FSR Pin

DLB	FSRM	GSYNC	Source of Receive Frame Synchronization	FSR Pin Status
0	0	0 or 1	An external frame-synchronization signal enters the McBSP through the FSR pin. The signal is then inverted as determined by FSRP before being used as internal FSR.	Input
0	1	0	Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP before being driven out on the FSR pin.
0	1	1	Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the FSR pin is used to synchronize CLKG and generate FSG pulses.
1	0	0	Internal FSX drives internal FSR.	High impedance

Table 34-37. Select Sources to Provide the Receive Frame-Synchronization Signal and the Effect on the FSR Pin (continued)

DLB	FSRM	GSYNC	Source of Receive Frame Synchronization	FSR Pin Status
1	0 or 1	1	Internal FSX drives internal FSR.	Input. If the sample rate generator is running, external FSR is used to synchronize CLKG and generate FSG pulses.
1	1	0	Internal FSX drives internal FSR.	Output. Receive (same as transmit) frame synchronization is inverted as determined by FSRP before being driven out on the FSR pin.

34.8.16 Receive Frame-Synchronization Polarity

The FSRP bit (see Table 34-38) determines whether frame-synchronization pulses are active high or active low on the FSR pin.

Table 34-38. Register Bit Used to Set Receive Frame-Synchronization Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	2	FSRP	Receive frame-synchronization polarity		R/W	0
			FSRP = 0	Frame-synchronization pulse FSR is active high.		
			FSRP = 1	Frame-synchronization pulse FSR is active low.		

34.8.16.1 Frame-Synchronization Pulses, Clock Signals, and Their Polarities

Receive frame-synchronization pulses can be generated internally by the sample rate generator (see Section 34.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSRM, in PCR. FSR is also affected by the GSYNC bit in SRGR2. For information about the effects of FSRM and GSYNC, see Section 34.8.15. Similarly, receive clocks can be selected to be inputs or outputs by programming the mode bit, CLKRM, in the PCR (see Section 34.8.17).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

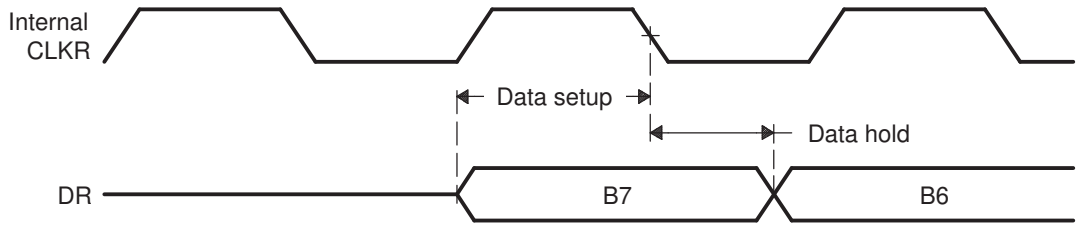
FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

MCLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge. Figure 34-48 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 34-48. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge



Set the SRG Frame-Synchronization Period and Pulse Width

34.8.16.2 Frame-Synchronization Period and the Frame-Synchronization Pulse Width

The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0. Table 34-39 shows settings for FPER and FWID.

Figure 34-49 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

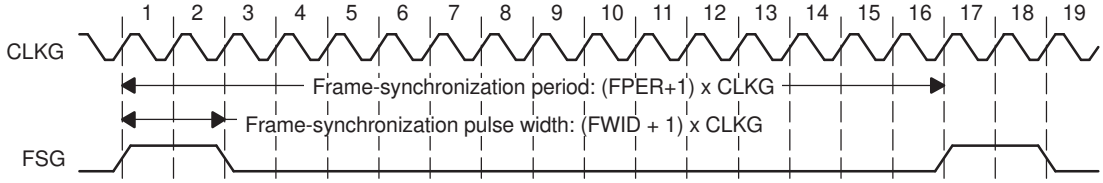
Table 34-39. Register Bits Used to Set the SRG Frame-Synchronization Period and Pulse Width

Register	Bit	Name	Function	Type	Reset Value
SRGR2	11-0	FPER	Sample rate generator frame-synchronization period For the frame-synchronization signal FSG, (FPER + 1) determines the period from the start of a frame-synchronization pulse to the start of the next frame-synchronization pulse. Range for (FPER + 1): 1 to 4096 CLKG cycles	R/W	0000 0000 0000
SRGR1	15-8	FWID	Sample rate generator frame-synchronization pulse width This field plus 1 determines the width of each frame-synchronization pulse on FSG.	R/W	0000 0000

Table 34-39. Register Bits Used to Set the SRG Frame-Synchronization Period and Pulse Width (continued)

Register	Bit	Name	Function	Type	Reset Value
			Range for (FWID + 1):		
			1 to 256 CLKG cycles		

Figure 34-49. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods



When the sample rate generator comes out of reset, FSG is in its inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

34.8.17 Receive Clock Mode

Table 34-40 shows the settings for bits used to set receive clock mode.

Table 34-40. Register Bits Used to Set the Receive Clock Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	8	CLKRM	Receive clock mode		R/W	0
			Case 1: Digital loopback mode not set (DLB = 0) in SPCR1.			
			CLKRM = 0	The MCLKR pin is an input pin that supplies the internal receive clock (MCLKR).		
			CLKRM = 1	Internal MCLKR is driven by the sample rate generator of the McBSP. The MCLKR pin is an output pin that reflects internal MCLKR.		
			Case 2: Digital loopback mode set (DLB = 1) in SPCR1.			
			CLKRM = 0	The MCLKR pin is in the high impedance state. The internal receive clock (MCLKR) is driven by the internal transmit clock (CLKX). Internal CLKX is derived according to the CLKXM bit of PCR.		
			CLKRM = 1	Internal MCLKR is driven by internal CLKX. The MCLKR pin is an output pin that reflects internal MCLKR. Internal CLKX is derived according to the CLKXM bit of PCR.		
SPCR1	15	DLB	Digital loopback mode		R/W	00
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled. The receive signals, including the receive frame-synchronization signal, are connected internally through multiplexers to the corresponding transmit signals.		

Table 34-40. Register Bits Used to Set the Receive Clock Mode (continued)

Register	Bit	Name	Function		Type	Reset Value
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode.		
			CLKSTP = 10b	Clock stop mode enabled without clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		
			CLKSTP = 11b	Clock stop mode enabled with clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		

34.8.17.1 Selecting a Source for the Receive Clock and a Data Direction for the MCLKR Pin

Table 34-41 shows how you can select various sources to provide the receive clock signal and affect the MCLKR pin. The polarity of the signal on the MCLKR pin is determined by the CLKRP bit.

In the digital loopback mode (DLB = 1), the transmit clock signal is used as the receive clock signal.

Also, in the clock stop mode, the internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

Table 34-41. Receive Clock Signal Source Selection

DLB in SPCR1	CLKRM in PCR	Source of Receive Clock	MCLKR Pin Status
0	0	The MCLKR pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP before being used.	Input
0	1	The sample rate generator clock (CLKG) drives internal MCLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the MCLKR pin.
1	0	Internal CLKX drives internal MCLKR. To configure CLKX, see Section 34.9.19.	High impedance
1	1	Internal CLKX drives internal MCLKR. To configure CLKX, see Section 34.9.19.	Output. Internal MCLKR (same as internal CLKX) is inverted as determined by CLKRP before being driven out on the MCLKR pin.

34.8.18 Receive Clock Polarity

Table 34-42. Register Bit Used to Set Receive Clock Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	0	CLKRP	Receive clock polarity		R/W	0
			CLKRP = 0	Receive data sampled on falling edge of MCLKR		
			CLKRP = 1	Receive data sampled on rising edge of MCLKR		

34.8.18.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Receive frame-synchronization pulses can be generated internally by the sample rate generator (see Section 34.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSRM, in PCR. FSR is also affected by the GSYNC bit in SRGR2. For information about the effects of FSRM and GSYNC, see Section 34.8.15. Similarly, receive clocks can be selected to be inputs or outputs by programming the mode bit, CLKRM, in the PCR (see Section 34.8.17).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

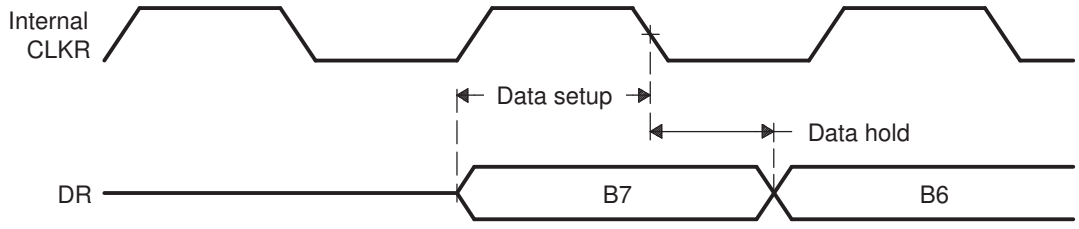
FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge. Figure 34-50 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 34-50. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge



34.8.19 SRG Clock Divide-Down Value

Table 34-43. Register Bits Used to Set the Sample Rate Generator (SRG) Clock Divide-Down Value

Register	Bit	Name	Function	Type	Reset Value
SRGR1	7-0	CLKGDV	Sample rate generator clock divide-down value The input clock of the sample rate generator is divided by (CLKGDV + 1) to generate the required sample rate generator clock frequency. The default value of CLKGDV is 1 (divide input clock by 2).	R/W	0000 0001

34.8.19.1 Sample Rate Generator Clock Divider

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to 1/(CLKGDV + 1) of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. When CLKGDV is odd or equal to 0, the CLKG duty cycle is 50%. When CLKGDV is an even value, 2p, representing an odd divide-down, the high-state duration is p + 1 cycles and the low-state duration is p cycles.

34.8.20 SRG Clock Synchronization Mode

For more details on using the clock synchronization feature, see Section 34.4.3.

Table 34-44. Register Bit Used to Set the SRG Clock Synchronization Mode

Register	Bit	Name	Function	Type	Reset Value
SRGR2	15	GSYNC	Sample rate generator clock synchronization GSYNC is used only when the input clock source for the sample rate generator is external—on the MCLKR or MCLKX pin. GSYNC = 0: The sample rate generator clock (CLKG) is free running. CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles. GSYNC = 1: Clock synchronization is performed. When a pulse is detected on the FSR pin: • CLKG is adjusted as necessary so that it is synchronized with the input clock on the MCLKR or MCLKX pin. • FSG pulses. FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored.	R/W	0

34.8.21 SRG Clock Mode (Choose an Input Clock)

Table 34-45. Register Bits Used to Set the SRG Clock Mode (Choose an Input Clock)

Register	Bit	Name	Function		Type	Reset Value
PCR	7	SCLKME	Sample rate generator clock mode		R/W	0
SRGR2	13	CLKSM			R/W	1
			SCLKME = 0 CLKSM = 0	Reserved		
			SCLKME = 0 CLKSM = 1	Sample rate generator clock derived from LSPCLK (default)		
			SCLKME = 1 CLKSM = 0	Sample rate generator clock derived from MCLKR pin		
			SCLKME = 1 CLKSM = 1	Sample rate generator clock derived from MCLKX pin		

34.8.21.1 SRG Clock Mode

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock. Table 34-45 shows the four possible sources of the input clock. For more details on generating CLKG, see Section 34.4.1.1.

34.8.22 SRG Input Clock Polarity

Table 34-46. Register Bits Used to Set the SRG Input Clock Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	1	CLKXP	MCLKX pin polarity		R/W	0
			CLKXP determines the input clock polarity when the MCLKX pin supplies the input clock (SCLKME = 1 and CLKSM = 1).			
			CLKXP = 0	Rising edge on MCLKX pin generates transitions on CLKG and FSG.		
			CLKXP = 1	Falling edge on MCLKX pin generates transitions on CLKG and FSG.		
PCR	0	CLKRP	MCLKR pin polarity		R/W	0
			CLKRP determines the input clock polarity when the MCLKR pin supplies the input clock (SCLKME = 1 and CLKSM = 0).			
			CLKRP = 0	Falling edge on MCLKR pin generates transitions on CLKG and FSG.		
			CLKRP = 1	Rising edge on MCLKR pin generates transitions on CLKG and FSG.		

34.8.22.1 Using CLKXP/CLKRP to Choose an Input Clock Polarity

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the CPU clock or from an external clock on the CLKX or MCLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKXP for the MCLKX pin, CLKRP for the MCLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

34.9 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP/transmitter in reset (see Section 34.9.2).
2. Program the McBSP registers for the desired transmitter operation (see Section 34.9.1).
3. Take the transmitter out of reset (see Section 34.9.2).

34.9.1 Programming the McBSP Registers for the Desired Transmitter Operation

The following is a list of important tasks to be performed when you are configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

- Global behavior:
  - Set the transmitter pins to operate as McBSP pins.
  - Enable/disable the digital loopback mode.
  - Enable/disable the clock stop mode.
  - Enable/disable transmit multichannel selection.
- Data behavior:
  - Choose 1 or 2 phases for the transmit frame.
  - Set the transmit word length(s).
  - Set the transmit frame length.
  - Enable/disable the transmit frame-synchronization ignore function.
  - Set the transmit companding mode.
  - Set the transmit data delay.

  - Set the transmit DXENA mode.
  - Set the transmit interrupt mode.
- Frame-synchronization behavior:
  - Set the transmit frame-synchronization mode.
  - Set the transmit frame-synchronization polarity.
  - Set the SRG frame-synchronization period and pulse width.
- Clock behavior:
  - Set the transmit clock mode.
  - Set the transmit clock polarity.
  - Set the SRG clock divide-down value.
  - Set the SRG clock synchronization mode.
  - Set the SRG clock mode (choose an input clock).
  - Set the SRG input clock polarity.

34.9.2 Resetting and Enabling the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset). Table 34-47 describes the bits used for both of these steps.

Table 34-47. Register Bits Used to Place Transmitter in Reset Field Descriptions

Register	Bit	Field	Value	Description
SPCR2	7	FRST		Frame-synchronization logic reset
			0	Frame-synchronization logic is reset. The sample rate generator does not generate frame-synchronization signal FSG, even if GRST = 1.
			1	Frame-synchronization is enabled. If GRST = 1, frame-synchronization signal FSG is generated after (FPER + 1) number of CLKG clock cycles; all frame counters are loaded with their programmed values.
SPCR2	6	GRST		Sample rate generator reset
			0	Sample rate generator is reset. If GRST = 0 due to a device reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive).
			1	Sample rate generator is enabled. CLKG is driven according to the configuration programmed in the sample rate generator registers (SRGR[1,2]). If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers.
SPCR2	0	XRST		Transmitter reset
			0	The serial port transmitter is disabled and in the reset state.
			1	The serial port transmitter is enabled.

34.9.2.1 Reset Considerations

The serial port can be reset in the following two ways:

1. A DSP reset ($\overline{\text{XRS}}$ signal driven low) places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST = FRST = RRST = XRST = 0, keeping the entire serial port in the reset state.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the serial port control registers. The sample rate generator can be reset directly using the GRST bit in SPCR2.
3. When using the DMA, the order in which McBSP events must occur is important. DMA channel and peripheral interrupts must be configured prior to releasing the McBSP transmitter from reset.

   The reason for this is that an XRDY is fired when XRST = 1. The XRDY signals the DMA to start copying data from the buffer into the transmit register. If the McBSP transmitter is released from reset before the DMA channel and peripheral interrupts are configured, the XRDY signals before the DMA channel can receive the signal; therefore, the DMA does not move the data from the buffer to the

transmit register. The DMA PERINTFLG is edge-sensitive and will fail to recognize the XRDY, which is continuously high.

For more details about McBSP reset conditions and effects, see Section 34.10.2.

34.9.3 Set the Transmitter Pins to Operate as McBSP Pins

To configure a pin for its McBSP function , you should configure the bits of the GPxMUXn register appropriately. In addition to this, bits 12 and 13 of the PCR register must be set to 0. These bits are defined as reserved.

34.9.4 Digital Loopback Mode

The DLB bit determines whether the digital loopback mode is on. DLB is described in Table 34-48.

Table 34-48. Register Bit Used to Enable/Disable the Digital Loopback Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	15	DLB	Digital loopback mode		R/W	0
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled.		

34.9.4.1 Digital Loopback Mode

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals, as shown in Table 34-49. This mode allows testing of serial port code with a single DSP device; the McBSP receives the data it transmits.

Table 34-49. Receive Signals Connected to Transmit Signals in Digital Loopback Mode

This Receive Signal	Is Fed Internally by This Transmit Signal
DR (receive data)	DX (transmit data)
FSR (receive frame synchronization)	FSX (transmit frame synchronization)
MCLKR (receive clock)	CLKX (transmit clock)

34.9.5 Clock Stop Mode

The CLKSTP bits determine whether the clock stop mode is on. CLKSTP is described in Table 34-50.

Table 34-50. Register Bits Used to Enable/Disable the Clock Stop Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode.		
			CLKSTP = 10b	Clock stop mode enabled without clock delay		
			CLKSTP = 11b	Clock stop mode enabled with clock delay		

34.9.5.1 Clock Stop Mode

The clock stop mode supports the SPI master-slave protocol. If you do not plan to use the SPI protocol, you can clear CLKSTP to disable the clock stop mode.

In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). The CLKXP bit determines whether the starting edge of the clock on the MCLKX pin is rising or falling. The CLKRP bit determines whether receive data is sampled on the rising or falling edge of the clock shown on the MCLKR pin.

Table 34-51 summarizes the impact of CLKSTP, CLKXP, and CLKRP on serial port operation. In the clock stop mode, the receive clock is tied internally to the transmit clock, and the receive frame-synchronization signal is tied internally to the transmit frame-synchronization signal.

Table 34-51. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme

Bit Settings	Clock Scheme
CLKSTP = 00b or 01b CLKXP = 0 or 1 CLKRP = 0 or 1	Clock stop mode disabled. Clock enabled for non-SPI mode.
CLKSTP = 10b CLKXP = 0 CLKRP = 0	Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR.
CLKSTP = 11b CLKXP = 0 CLKRP = 1	Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 10b CLKXP = 1 CLKRP = 0	High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 11b CLKXP = 1 CLKRP = 1	High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR.

34.9.6 Transmit Multichannel Selection Mode

For more details, see Section 34.6.7.

Table 34-52. Register Bits Used to Enable/Disable Transmit Multichannel Selection

Register	Bit	Name	Function		Type	Reset Value
MCR2	1-0	XMCM	Transmit multichannel selection		R/W	00
			XMCM = 00b	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.		
			XMCM = 01b	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked.		
				The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs.		
			XMCM = 10b	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (XCERs).		
				The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs.		
			XMCM = 11b	This mode is used for symmetric transmission and reception.		
				All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (XCERs).		
				The XMCME bit determines whether 32 channels or 128 channels are selectable in RCERs and XCERs.		

34.9.7 XCERs Used in the Transmit Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the XCERs depends on whether 32 or 128 channels are individually selectable, as defined by the XMCME bit. These two cases are shown in Table 34-97. The table shows which block of channels is assigned to each XCER that is used. For each XCER, the table shows which channel is assigned to each of the bits.

NOTE: When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive channel enable registers (RCERs) to enable channels and uses the XCERs to unmask channels for transmission.

Table 34-53. Use of the Transmit Channel Enable Registers

Number of Selectable Channels	Block Assignments		Channel Assignments	
	XCERx	Block Assigned	Bit in XCERx	Channel Assigned
32 (XMCME = 0)	XCERA	Channels n to (n + 15)	XCE0	Channel n
			XCE1	Channel (n + 1)
			XCE2	Channel (n + 2)
			:	:
		When XMCM = 01b or 10b, the block of channels is chosen with the XPABLK bits. When XMCM = 11b, the block is chosen with the RPABLK bits.	XCE15	Channel (n + 15)

Table 34-53. Use of the Transmit Channel Enable Registers (continued)

Number of Selectable Channels	Block Assignments		Channel Assignments	
	XCERx	Block Assigned	Bit in XCERx	Channel Assigned
	XCERB	Channels m to (m + 15)	XCE0	Channel m
			XCE1	Channel (m + 1)
			XCE2	Channel (m + 2)
			:	:
		When XMCM = 01b or 10b, the block of channels is chosen with the XPBBLK bits. When XMCM = 11b, the block is chosen with the RPBBLK bits.	XCE15	Channel (m + 15)
128 (XMCME = 1)	XCERA	Block 0	XCE0	Channel 0
			XCE1	Channel 1
			XCE2	Channel 2
			:	:
			XCE15	Channel 15
	XCERB	Block 1	XCE0	Channel 16
			XCE1	Channel 17
			XCE2	Channel 18
			:	:
			XCE15	Channel 31
	XCERC	Block 2	XCE0	Channel 32
			XCE1	Channel 33

Table 34-53. Use of the Transmit Channel Enable Registers (continued)

Number of Selectable Channels	Block Assignments		Channel Assignments	
	XCERx	Block Assigned	Bit in XCERx	Channel Assigned
	XCERH	Block 7	XCE0	Channel 112
			XCE1	Channel 113
			XCE2	Channel 114
			:	:
			XCE15	Channel 127

34.9.8 Transmit Frame Phases

Table 34-54. Register Bit Used to Choose 1 or 2 Phases for the Transmit Frame

Register	Bit	Name	Function	Type	Reset Value
XCR2	15	XPHASE	Transmit phase number	R/W	0
			Specifies whether the transmit frame has 1 or 2 phases.		
			XPHASE = 0 Single-phase frame		
			XPHASE = 1 Dual-phase frame		

34.9.9 Transmit Word Length(s)

Table 34-55. Register Bits Used to Set the Transmit Word Length(s)

Register	Bit	Name	Function	Type	Reset Value
XCR1	7-5	XWDLEN1	Transmit word length of frame phase 1	R/W	000
			XWDLEN1 = 000b 8 bits		
			XWDLEN1 = 001b 12 bits		
			XWDLEN1 = 010b 16 bits		
			XWDLEN1 = 011b 20 bits		
			XWDLEN1 = 100b 24 bits		
			XWDLEN1 = 101b 32 bits		
			XWDLEN1 = 11Xb Reserved		
XCR2	7-5	XWDLEN2	Transmit word length of frame phase 2	R/W	000
			XWDLEN2 = 000b 8 bits		
			XWDLEN2 = 001b 12 bits		
			XWDLEN2 = 010b 16 bits		
			XWDLEN2 = 011b 20 bits		
			XWDLEN2 = 100b 24 bits		
			XWDLEN2 = 101b 32 bits		
			XWDLEN2 = 11Xb Reserved		

34.9.9.1 Word Length Bits

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame, and XWDLEN2 determines the word length in phase 2 of the frame.

34.9.10 Transmit Frame Length

Table 34-56. Register Bits Used to Set the Transmit Frame Length

Register	Bit	Name	Function		Type	Reset Value
XCR1	14-8	XFRLEN1	Transmit frame length 1		R/W	000 0000
			(XFRLEN1 + 1) is the number of serial words in phase 1 of the transmit frame.			
			XFRLEN1 = 000 0000	1 word in phase 1		
			XFRLEN1 = 000 0001	2 words in phase 1		
			|	|		
			|	|		
			XFRLEN1 = 111 1111	128 words in phase 1		
XCR2	14-8	XFRLEN2	Transmit frame length 2		R/W	000 0000
			If a dual-phase frame is selected, (XFRLEN2 + 1) is the number of serial words in phase 2 of the transmit frame.			
			XFRLEN2 = 000 0000	1 word in phase 2		
			XFRLEN2 = 000 0001	2 words in phase 2		
			|	|		
			|	|		
			XFRLEN2 = 111 1111	128 words in phase 2		

34.9.10.1 Selected Frame Length

The transmit frame length is the number of serial words in the transmit frame. Each frame can have one or two phases, depending on the value that you load into the XPHASE bit.

If a single-phase frame is selected (XPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (XPHASE = 1), the frame length is the length of phase 1 plus the length of phase 2.

The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 34-57 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

NOTE: Program the XFRLEN fields with [*w minus 1*], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 34-57. How to Calculate Frame Length

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	0 ≤ XFRLEN1 ≤ 127	Don't care	(XFRLEN1 + 1) words
1	0 ≤ XFRLEN1 ≤ 127	0 ≤ XFRLEN2 ≤ 127	(XFRLEN1 + 1) + (XFRLEN2 + 1) words

34.9.11 Enable/Disable the Transmit Frame-Synchronization Ignore Function

Table 34-58. Register Bit Used to Enable/Disable the Transmit Frame-Synchronization Ignore Function

Register	Bit	Name	Function		Type	Reset Value
XCR2	2	XFIG	Transmit frame-synchronization ignore		R/W	0
			XFIG = 0	An unexpected transmit frame-synchronization pulse causes the McBSP to restart the frame transfer.		
			XFIG = 1	The McBSP ignores unexpected transmit frame-synchronization pulses.		

34.9.11.1 Unexpected Frame-Synchronization Pulses and Frame-Synchronization Ignore

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse.

When XFIG = 1, normal transmission continues with unexpected frame-synchronization signals ignored.

When XFIG = 0 and an unexpected frame-synchronization pulse occurs, the serial port:

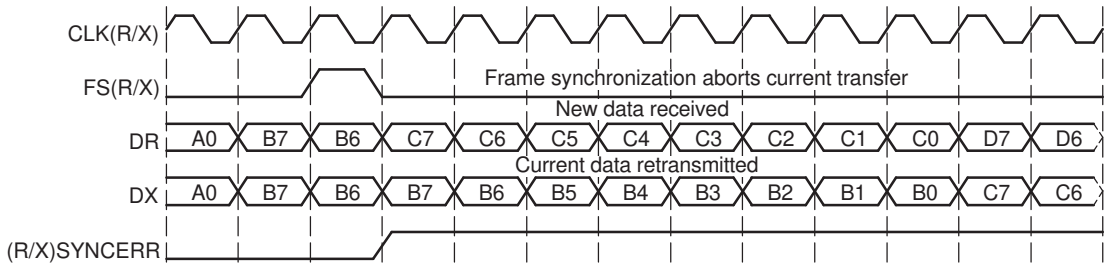
1. Aborts the present transmission
2. Sets XSYNCERR to 1 in SPCR2
3. Reinitiates transmission of the current word that was aborted

For more details about the frame-synchronization error condition, see Section 34.5.6.

34.9.11.2 Examples Showing the Effects of XFIG

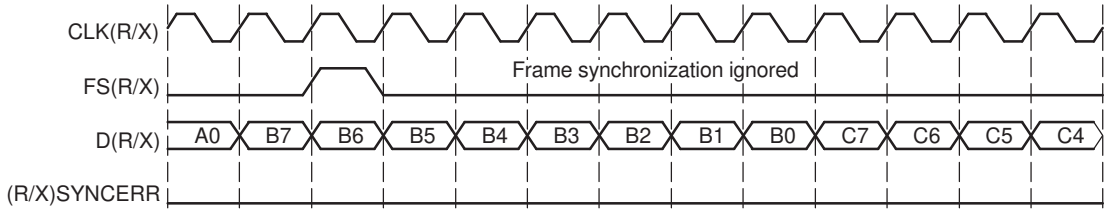
Figure 34-51 shows an example in which word B is interrupted by an unexpected frame-synchronization pulse when (R/X)FIG = 0. In the case of transmission, the transmission of B is aborted (B is lost). This condition is a transmit synchronization error, which sets the XSYNCERR bit. No new data has been written to DXR[1,2]; therefore, the McBSP transmits B again.

Figure 34-51. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 0



In contrast with Figure 34-51, Figure 34-52 shows McBSP operation when unexpected frame-synchronization signals are ignored (when (R/X)FIG = 1). Here, the transfer of word B is not affected by an unexpected frame-synchronization pulse.

Figure 34-52. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 1



34.9.12 Transmit Companding Mode

Table 34-59. Register Bits Used to Set the Transmit Companding Mode

Register	Bit	Name	Function		Type	Reset Value
XCR2	4-3	XCOMPAND	Transmit companding mode		R/W	00
			Modes other than 00b are enabled only when the appropriate XWDLEN is 000b, indicating 8-bit data.			
			XCOMPAND = 00b	No companding, any size data, MSB transmitted first		
			XCOMPAND = 01b	No companding, 8-bit data, LSB transmitted first (for details, see Section 34.8.11.4, *Option to Receive LSB First*)		
			XCOMPAND = 10b	μ-law companding, 8-bit data, MSB transmitted first		
			XCOMPAND = 11b	A-law companding, 8-bit data, MSB transmitted first		

34.9.12.1 Companding

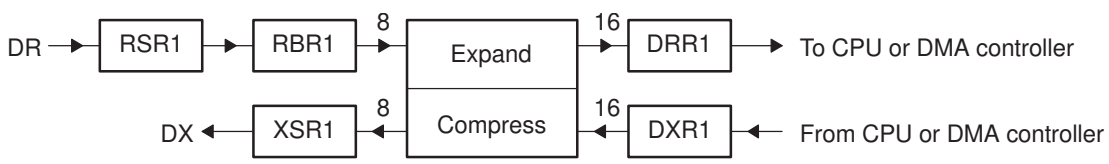
Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 34-53 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to twos-complement format.

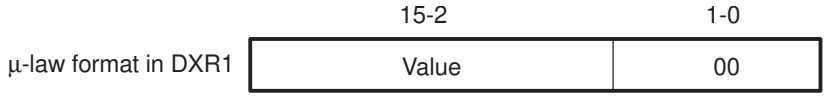
Figure 34-53. Companding Processes for Reception and for Transmission



34.9.12.2 Format for Data To Be Compressed

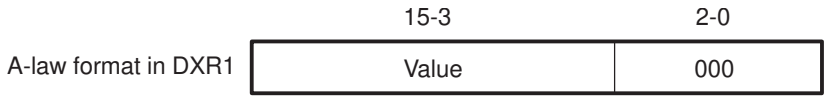
For transmission using μ-law compression, make sure the 14 data bits are left-justified in DXR1, with the remaining two low-order bits filled with 0s as shown in Figure 34-54.

Figure 34-54. μ-Law Transmit Data Companding Format



For transmission using A-law compression, make sure the 13 data bits are left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 34-55.

Figure 34-55. A-Law Transmit Data Companding Format



34.9.12.3 Capability to Compand Internal Data

If the McBSP is otherwise unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. See Section 34.3.2.2, *Capability to Compand Internal Data*.

34.9.12.4 Option to Transmit LSB First

Normally, the McBSP transmit or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits and LSB-first ordering is done.

34.9.13 Transmit Data Delay

Table 34-60. Register Bits Used to Set the Transmit Data Delay

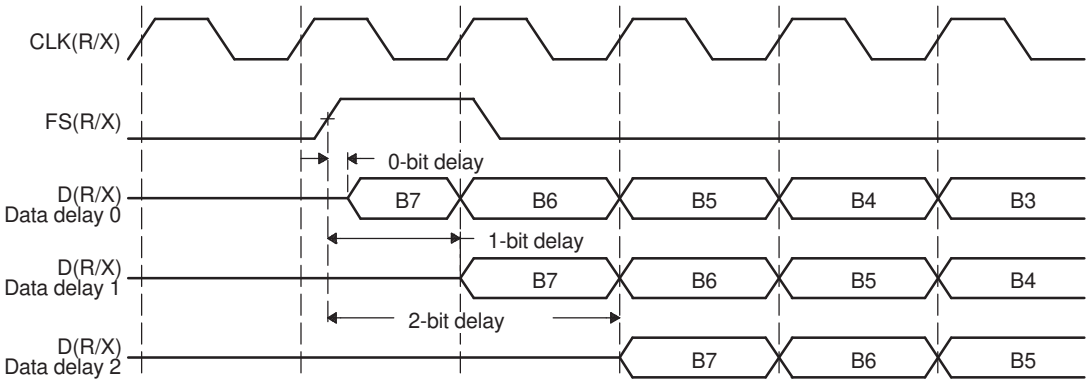
Register	Bit	Name	Function		Type	Reset Value
XCR2	1-0	XDATDLY	Transmitter data delay		R/W	00
			XDATDLY = 00	0-bit data delay		
			XDATDLY = 01	1-bit data delay		
			XDATDLY = 10	2-bit data delay		
			XDATDLY = 11	Reserved		

34.9.13.1 Data Delay

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if necessary. This delay is called data delay.

XDATDLY specifies the data delay for transmission. The range of programmable data delay is zero to two bit-clocks (XDATDLY = 00b-10b), as described in Table 34-60 and Figure 34-56. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 34-56. Range of Programmable Data Delay



34.9.13.2 0-Bit Data Delay

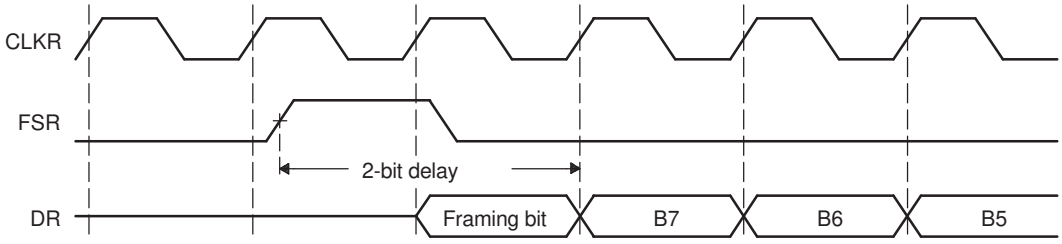
Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of serial clock internal CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data can be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception this problem is solved because receive data is sampled on the first falling edge of MCLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus DX. The transmitter then asynchronously detects the frame synchronization, FSX, going active high and immediately starts driving the first bit to be transmitted on the DX pin.

34.9.13.3 2-Bit Data Delay

A data delay of two bit-periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in the following figure. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 34-57. 2-Bit Data Delay Used to Skip a Framing Bit



34.9.14 Transmit DXENA Mode

Table 34-61 shows which register bit enables the Transmit DXENA (DX Delay Enabler) Mode.

Table 34-61. Register Bit Used to Set the Transmit DXENA (DX Delay Enabler) Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	7	DXENA	DX delay enabler mode		R/W	0
			DXENA = 0	DX delay enabler is off.		
			DXENA = 1	DX delay enabler is on.		

The DXENA bit controls the delay enabler on the DX pin. Set DXENA to enable an extra delay for turn-on time. This bit does not control the data itself, so only the first bit is delayed.

If you tie together the DX pins of multiple McBSPs, make sure DXENA = 1 to avoid having more than one McBSP transmit on the data line at one time.

34.9.15 Transmit Interrupt Mode

The transmitter interrupt (XINT) signals the CPU of changes to the serial port status. Four options exist for configuring this interrupt. The options are set by the transmit interrupt mode bits, XINTM, in SPCR2.

Table 34-62. Register Bits Used to Set the Transmit Interrupt Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR2	5-4	XINTM	Transmit interrupt mode		R/W	00
			XINTM = 00	XINT generated when XRDY changes from 0 to 1.		
			XINTM = 01	XINT generated by an end-of-block or end-of-frame condition in a transmit multichannel selection mode. In any of the transmit multichannel selection modes, interrupt after every 16-channel block boundary has been crossed within a frame and at the end of the frame. For details, see Section 34.6.8. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.		
			XINTM = 10	XINT generated by a new transmit frame-synchronization pulse. Interrupt on detection of each transmit frame-synchronization pulse. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending it to the CPU via XINT.		
			XINTM = 11	XINT generated when XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR can be read to detect this condition. For more information on using XSYNCERR, see Section 34.5.6.		

34.9.16 Transmit Frame-Synchronization Mode

Table 34-63 shows which register bits enable the Transmit Frame-Synchronization Mode.

Table 34-63. Register Bits Used to Set the Transmit Frame-Synchronization Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	11	FSXM	Transmit frame-synchronization mode		R/W	0
			FSXM = 0	Transmit frame synchronization is supplied by an external source via the FSX pin.		
			FSXM = 1	Transmit frame synchronization is supplied by the McBSP, as determined by the FSGM bit of SRGR2.		
SRGR2	12	FSGM	Sample rate generator transmit frame-synchronization mode		R/W	0
			Used when FSXM = 1 in PCR.			
			FSGM = 0	The McBSP generates a transmit frame-synchronization pulse when the content of DXR[1,2] is copied to XSR[1,2].		
			FSGM = 1	The transmitter uses frame-synchronization pulses generated by the sample rate generator. Program the FWID bits to set the width of each pulse. Program the FPER bits to set the frame-synchronization period.		

Table 34-64 shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

- External frame-synchronization input
- Sample rate generator frame-synchronization signal (FSG)
- Internal signal that indicates a DXR-to-XSR copy has been made

Table 34-64 also shows the effect of each bit setting on the FSX pin. The polarity of the signal on the FSX pin is determined by the FSXP bit.

Table 34-64. How FSXM and FSGM Select the Source of Transmit Frame-Synchronization Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	FSX Pin Status
0	0 or 1	An external frame-synchronization signal enters the McBSP through the FSX pin. The signal is then inverted by FSXP before being used as internal FSX.	Input
1	1	Internal FSX is driven by the sample rate generator frame-synchronization signal (FSG).	Output. FSG is inverted by FSXP before being driven out on FSX pin.
1	0	A DXR-to-XSR copy causes the McBSP to generate a transmit frame-synchronization pulse that is 1 cycle wide.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP before being driven out on FSX pin.

34.9.16.1 Other Considerations

If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the FSR pin. For more details, see Section 34.4.3.

In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master and must provide a slave-enable signal ($\overline{\text{SPISTE}}$) on the FSX pin, make sure that FSXM = 1 and FSGM = 0 so that FSX is an output and is driven active for the duration of each transmission. If the McBSP is a slave, make sure that FSXM = 0 so that the McBSP can receive the slave-enable signal on the FSX pin.

34.9.17 Transmit Frame-Synchronization Polarity

Table 34-65 shows which register bits enable the Transmit Frame-Synchronization Polarity.

Table 34-65. Register Bit Used to Set Transmit Frame-Synchronization Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	3	FSXP	Transmit frame-synchronization polarity		R/W	0
			FSXP = 0	Frame-synchronization pulse FSX is active high.		
			FSXP = 1	Frame-synchronization pulse FSX is active low.		

34.9.17.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Transmit frame-synchronization pulses can be generated internally by the sample rate generator (see Section 34.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSXM, in PCR. FSX is also affected by the FSGM bit in SRGR2. For information about the effects of FSXM and FSGM, see Section 34.9.16). Similarly, transmit clocks can be selected to be inputs or outputs by programming the mode bit, CLKXM, in the PCR (see Section 34.9.19).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

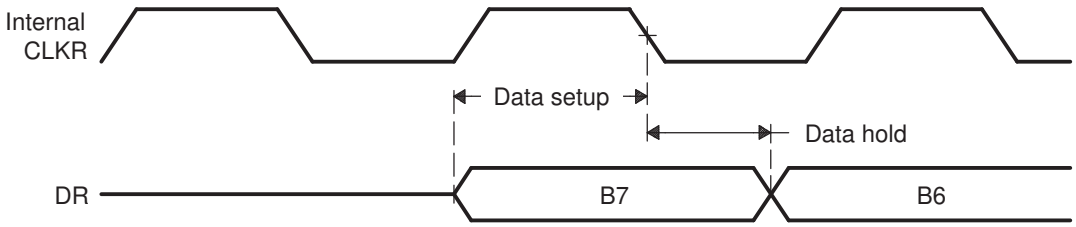
FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected and the polarity bit FS(R/X)P = 1, the internal active-high frame-synchronization signals are inverted before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge. Figure 34-58 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 34-58. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge



34.9.18 SRG Frame-Synchronization Period and Pulse Width

Table 34-66 shows which register bits set the SRG Frame-Synchronization Period and Pulse Width.

Table 34-66. Register Bits Used to Set SRG Frame-Synchronization Period and Pulse Width

Register	Bit	Name	Function	Type	Reset Value
SRGR2	11-0	FPER	Sample rate generator frame-synchronization period	R/W	0000 0000 0000
			For the frame-synchronization signal FSG, (FPER + 1) determines the period from the start of a frame-synchronization pulse to the start of the next frame-synchronization pulse.		
			Range for (FPER + 1): 1 to 4096 CLKG cycles.		
SRGR1	15-8	FWID	Sample rate generator frame-synchronization pulse width	R/W	0000 0000
			This field plus 1 determines the width of each frame-synchronization pulse on FSG.		
			Range for (FWID + 1): 1 to 256 CLKG cycles.		

34.9.18.1 Frame-Synchronization Period and Frame-Synchronization Pulse Width

The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

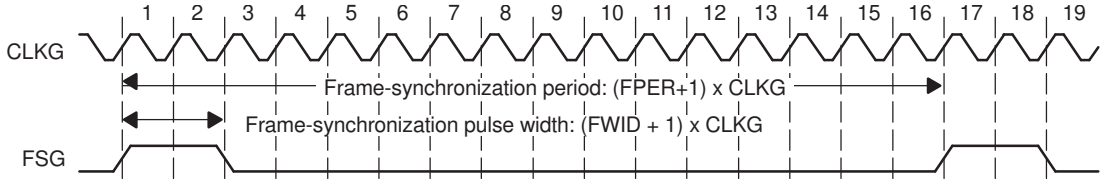
On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 34-59 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

Figure 34-59. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods



When the sample rate generator comes out of reset, FSG is in its inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

34.9.19 Transmit Clock Mode

Table 34-67 shows which register bits can set the Transmit Clock Mode.

Table 34-67. Register Bit Used to Set the Transmit Clock Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	9	CLKXM	Transmit clock mode		R/W	0
			CLKXM = 0	The transmitter gets its clock signal from an external source via the MCLKX pin.		
			CLKXM = 1	The MCLKX pin is an output pin driven by the sample rate generator of the McBSP.		

34.9.19.1 Selecting a Source for the Transmit Clock and a Data Direction for the MCLKX pin

Table 34-68 shows how the CLKXM bit selects the transmit clock and the corresponding status of the MCLKX pin. The polarity of the signal on the MCLKX pin is determined by the CLKXP bit.

Table 34-68. How the CLKXM Bit Selects the Transmit Clock and the Corresponding Status of the MCLKX pin

CLKXM in PCR	Source of Transmit Clock	MCLKX pin Status
0	Internal CLKX is driven by an external clock on the MCLKX pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the sample rate generator clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on CLKX.

34.9.19.2 Other Considerations

If the sample rate generator creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the FSR pin. For more details, see Section 34.4.3.

In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master, make sure that CLKXM = 1 so that CLKX is an output to supply the master clock to any slave devices. If the McBSP is a slave, make sure that CLKXM = 0 so that CLKX is an input to accept the master clock signal.

34.9.20 Transmit Clock Polarity

Table 34-69 shows which register bits set the Transmit Clock Polarity.

Table 34-69. Register Bit Used to Set Transmit Clock Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	1	CLKXP	Transmit clock polarity		R/W	0
			CLKXP = 0	Transmit data sampled on rising edge of CLKX.		
			CLKXP = 1	Transmit data sampled on falling edge of CLKX.		

34.9.20.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Transmit frame-synchronization pulses can be either generated internally by the sample rate generator (see Section 34.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSXM, in PCR. FSX is also affected by the FSGM bit in SRGR2. For information about the effects of FSXM and FSGM, see Section 34.9.16). Similarly, transmit clocks can be selected to be inputs or outputs by programming the mode bit, CLKXM, in the PCR (see Section 34.9.19).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

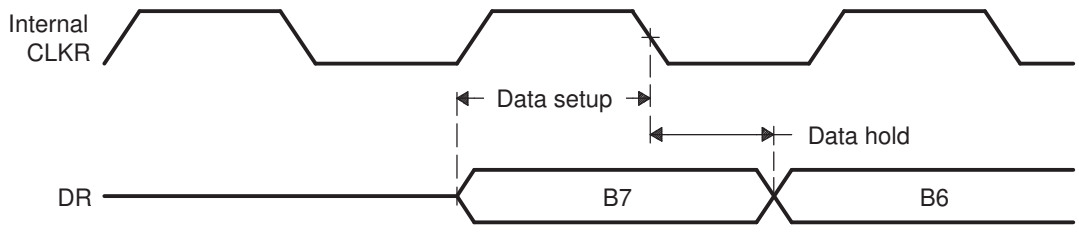
On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge (see Figure 34-58).

Figure 34-60 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 34-60. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge



34.10 Emulation and Reset Considerations

This section covers the following topics:

- How to program McBSP response to a breakpoint in the high-level language debugger (see Section 34.10.1)
- How to reset and initialize the various parts of the McBSP (see Section 34.10.2)

34.10.1 McBSP Emulation Mode

FREE and SOFT are special emulation bits in SPCR2 that determine the state of the McBSP when a breakpoint is encountered in the high-level language debugger. If FREE = 1, the clock continues to run upon a software breakpoint and data is still shifted out. When FREE = 1, the SOFT bit is a *don't care.*

If FREE = 0, the SOFT bit takes effect. If SOFT = 0 when breakpoint occurs, the clock stops immediately, aborting a transmission. If SOFT = 1 and a breakpoint occurs while transmission is in progress, the transmission continues until completion of the transfer and then the clock halts. These options are listed in Table 34-70.

The McBSP receiver functions in a similar fashion. If a mode other than the immediate stop mode (SOFT = FREE = 0) is chosen, the receiver continues running and an overrun error is possible.

Table 34-70. McBSP Emulation Modes Selectable with FREE and SOFT Bits of SPCR2

FREE	SOFT	McBSP Emulation Mode
0	0	Immediate stop mode (reset condition)
		The transmitter or receiver stops immediately in response to a breakpoint.
0	1	Soft stop mode
		When a breakpoint occurs, the transmitter stops after completion of the current word. The receiver is not affected.
1	0 or 1	Free run mode
		The transmitter and receiver continue to run when a breakpoint occurs.

34.10.2 Resetting and Initializing McBSPs

This section discusses in greater depth the MCBSP Reset and Initialization configurations.

34.10.2.1 McBSP Pin States: DSP Reset Versus Receiver/Transmitter Reset

Table 34-71 shows the state of McBSP pins when the serial port is reset due to direct receiver or transmitter reset on the 2833x device.

Table 34-71. Reset State of Each McBSP Pin

Pin	Possible State(s)[1]	State Forced by Device Reset	State Forced by Receiver/Transmitter Reset
Receiver reset (RRST = 0 and GRST = 1)			
MDRx	I	GPIO-input	Input
MCLKRx	I/O/Z	GPIO-input	Known state if input; MCLKR running if output
MFSRx	I/O/Z	GPIO-input	Known state if input; FSRP inactive state if output
Transmitter reset (XRST = 0 and GRST = 1)			
MDXx	O/Z	GPIO Input	High impedance
MCLKXx	I/O/Z	GPIO-input	Known state if input; CLKX running if output
MFSXx	I/O/Z	GPIO-input	Known state if input; FSXP inactive state if output

(1) In Possible State(s) column, I = Input, O = Output, Z = High impedance. In the 28x family, at device reset, all I/Os default to GPIO function and generally as inputs.

34.10.2.2 Device Reset, McBSP Reset, and Sample Rate Generator Reset

When the McBSP is reset in either of the above two ways, the machine is reset to its initial state, including reset of all counters and status bits. The receive status bits include RFULL, RRDY, and RSYNCERR. The transmit status bits include XEMPTY, XRDY, and XSYNCERR.

- Device reset. When the whole DSP is reset ($\overline{\text{XRS}}$ signal is driven low), all McBSP pins are in GPIO mode. When the device is pulled out of reset, the clock to the McBSP modules remains disabled.
- McBSP reset. When the receiver and transmitter reset bits, RRST and XRST, are loaded with 0s, the respective portions of the McBSP are reset and activity in the corresponding section of the serial port stops. Input-only pins such as MDRx, and all other pins that are configured as inputs are in a known state. The MFSRx and MFSXx pins are driven to their inactive state if they are not outputs. If the MCLKR and MCLKX pins are programmed as outputs, they are driven by CLKG, provided that GRST = 1. Lastly, the MDXx pin is in the high-impedance state when the transmitter and/or the device is reset.

  During normal operation, the sample rate generator is reset if the GRST bit is cleared. GRST must be 0 only when neither the transmitter nor the receiver is using the sample rate generator. In this case, the internal sample rate generator clock (CLKG) and its frame-synchronization signal (FSG) are driven inactive low.

  When the sample rate generator is not in the reset state (GRST = 1), pins MFSRx and MFSXx are in an inactive state when RRST = 0 and XRST = 0, respectively, even if they are outputs driven by FSG. This ensures that when only one portion of the McBSP is in reset, the other portion can continue operation when GRST = 1 and its frame synchronization is driven by FSG.
- Sample rate generator reset. The sample rate generator is reset when GRST is loaded with 0.

  When neither the transmitter nor the receiver is fed by CLKG and FSG, you can reset the sample rate generator by clearing GRST. In this case, CLKG and FSG are driven inactive low. If you then set GRST, CLKG starts and runs as programmed. Later, if GRST = 1, FSG pulses active high after the programmed number of CLKG cycles has elapsed.

34.10.2.3 McBSP Initialization Procedure

The serial port initialization procedure is as follows:

1. Make XRST = RRST = GRST = 0 in SPCR[1,2]. If coming out of a device reset, this step is not required.
2. While the serial port is in the reset state, program only the McBSP configuration registers (not the data registers) as required.
3. Wait for two clock cycles. This ensures proper internal synchronization.
4. Set up data acquisition as required (such as writing to DXR[1,2]).
5. Make XRST = RRST = 1 to enable the serial port. Make sure that as you set these reset bits, you do not modify any of the other bits in SPCR1 and SPCR2. Otherwise, you change the configuration you selected in step 2.
6. Set FRST = 1, if internally generated frame synchronization is required.
7. Wait two clock cycles for the receiver and transmitter to become active.

Alternatively, on either write (step 1 or 5), the transmitter and receiver can be placed in or taken out of reset individually by modifying the desired bit.

The above procedure for reset/initialization can be applied in general when the receiver or transmitter must be reset during its normal operation and when the sample rate generator is not used for either operation.

NOTE:

1. The necessary duration of the active-low period of XRST or RRST is at least two MCLKR/CLKX cycles.
2. The appropriate bits in serial port configuration registers SPCR[1,2], PCR, RCR[1,2], XCR[1,2], and SRGR[1,2] must only be modified when the affected portion of the serial port is in its reset state.
3. In most cases, the data transmit registers (DXR[1,2]) must be loaded by the CPU or by the DMA controller only when the transmitter is enabled (XRST = 1). An exception to this rule is when these registers are used for companding internal data (see Section 34.3.2.2).
4. The bits of the channel control registers—MCR[1,2], RCER[A-H], XCER[A-H]—can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.

34.10.2.4 Resetting the Transmitter While the Receiver is Running

Example 34-1 shows values in the control registers that reset and configure the transmitter while the receiver is running.

Example 34-1. Resetting and Configuring McBSP Transmitter While McBSP Receiver Running

```
SPCR1 = 0001h SPCR2 = 0030h ; The receiver is running with the receive interrupt (RINT) triggered by
the ; receiver ready bit (RRDY). The transmitter is in its reset state . The transmit interrupt
(XINT) will be triggered by the transmit frame-
sync ; error bit (XSYNCERR). PCR = 0900h ; Transmit frame synchronization is generated internally
according to the ; FSGM bit of SRGR2. ; The transmit clock is driven by an external source. ; The
receive clock continues to be driven by sample rate generator. The input clock ; of the sample rate
generator is supplied by the CPU clock SRGR1 = 0001h SRGR2 = 2000h ; The CPU clock is the input clock
for the sample rate generator. The sample ; rate generator divides the CPU clock by 2 to generate its
output clock (CLKG). ; Transmit frame synchronization is tied to the automatic copying of data from ;
the DXR(s) to the XSR(s). XCR1 = 0740h XCR2 = 8321h ; The transmit frame has two phases. Phase 1 has
eight 16-bit words. Phase 2 ; has four 12-bit words. There is 1-
bit data delay between the start of a ; frame-
sync pulse and the first data bit ; transmitted. SPCR2 = 0031h ; The transmitter is taken out of
reset.
```

34.11 Data Packing Examples

This section shows two ways to implement data packing in the McBSP.

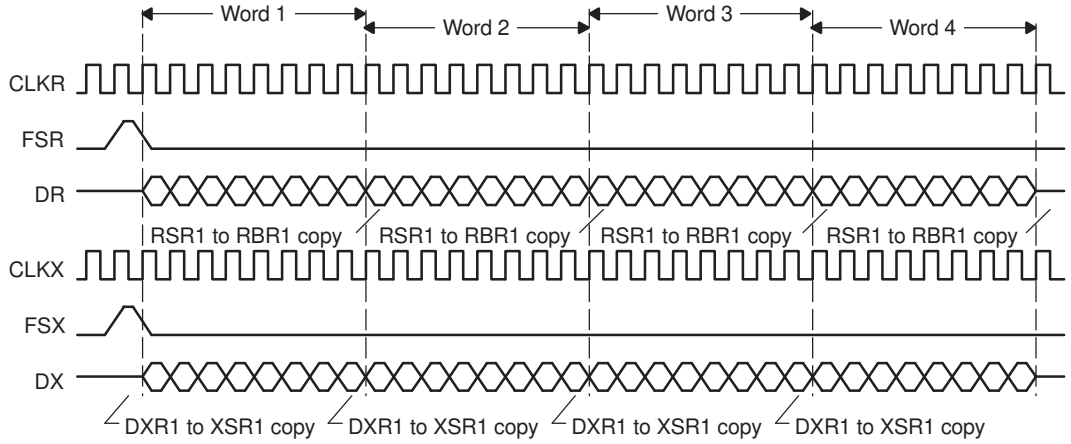
34.11.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to effectively pack data. For example, consider a situation where four 8-bit words are transferred in a single-phase frame as shown in Figure 34-61. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000011b: 4-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Four 8-bit data words are transferred to and from the McBSP by the CPU or by the DMA controller. Thus, four reads from DRR1 and four writes to DXR1 are necessary for each frame.

Figure 34-61. Four 8-Bit Data Words Transferred To/From the McBSP



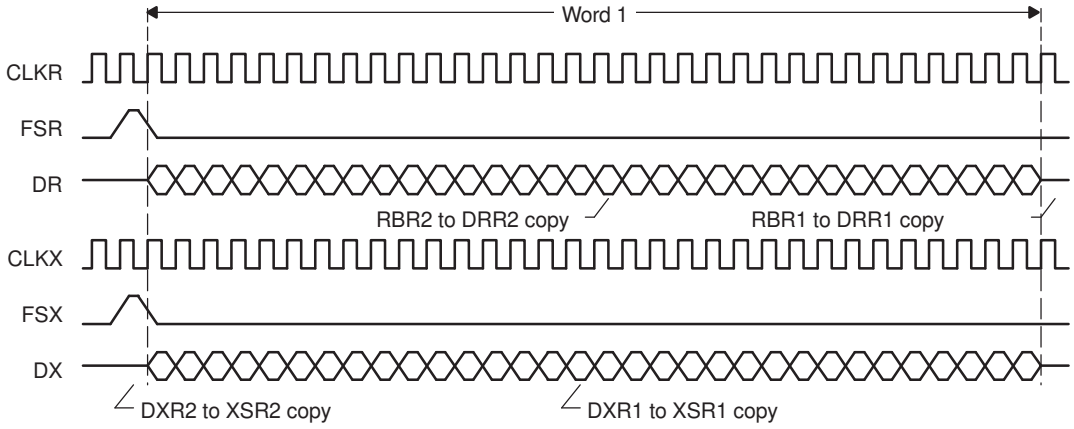
This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in Figure 34-62. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 101b: 32-bit word

Two 16-bit data words are transferred to and from the McBSP by the CPU or DMA controller. Thus, two reads, from DRR2 and DRR1, and two writes, to DXR2 and DXR1, are necessary for each frame. This results in only half the number of transfers compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

NOTE: When the word length is larger than 16 bits, make sure you access DRR2/DXR2 before you access DRR1/DXR1. McBSP activity is tied to accesses of DRR1/DXR1. During the reception of 24-bit or 32-bit words, read DRR2 and then read DRR1. Otherwise, the next RBR[1,2]-to-DRR[1,2] copy occurs before DRR2 is read. Similarly, during the transmission of 24-bit or 32-bit words, write to DXR2 and then write to DXR1. Otherwise, the next DXR[1,2]-to-XSR[1,2] copy occurs before DXR2 is loaded with new data.

Figure 34-62. One 32-Bit Data Word Transferred To/From the McBSP



34.11.2 Data Packing Using Word Length and the Frame-Synchronization Ignore Function

When there are multiple words per frame, you can implement data packing by increasing the word length (defining a serial word with more bits) and by ignoring frame-synchronization pulses. First, consider Figure 34-63, which shows the McBSP operating at the maximum packet frequency. Here, each frame only has a single 8-bit word. Notice the frame-synchronization pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

Figure 34-63. 8-Bit Data Words Transferred at Maximum Packet Frequency

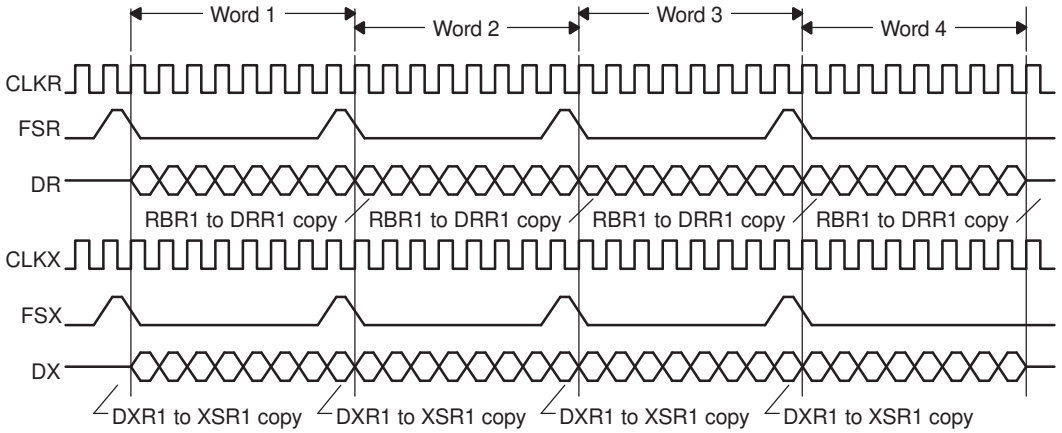


Figure 34-64 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-synchronization pulse. However, (R/X)FIG = 1 so that the McBSP ignores subsequent pulses. Only two read transfers or two write transfers are needed every 32 bits. This configuration effectively reduces the required bus bandwidth to half the bandwidth needed to transfer four 8-bit words.

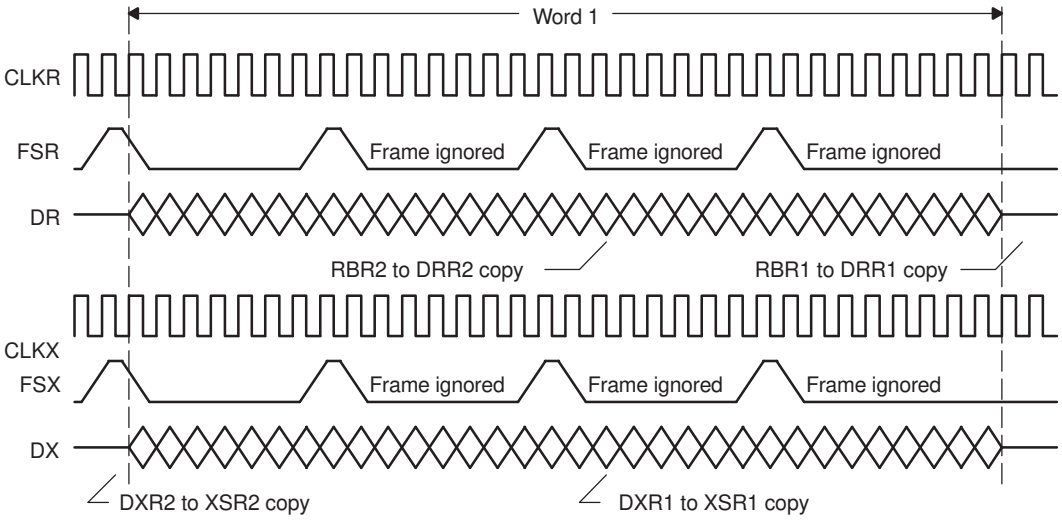
Figure 34-64. Configuring the Data Stream of Figure 34-63 as a Continuous 32-Bit Word



34.12 Interrupt Generation

McBSP registers can be programmed to receive and transmit data through DRR2/DRR1 and DXR2/DXR1 registers, respectively. The CPU can directly access these registers to move data from memory to these registers. Interrupt signals will be based on these register pair contents and its related flags. MRINT/MXINT will generate CPU interrupts for receive and transmit conditions.

34.12.1 McBSP Receive Interrupt Generation

In the McBSP module, data receive and error conditions generate two sets of interrupt signals. One set is used for the CPU and the other set is for DMA.

Figure 34-65. Receive Interrupt Generation

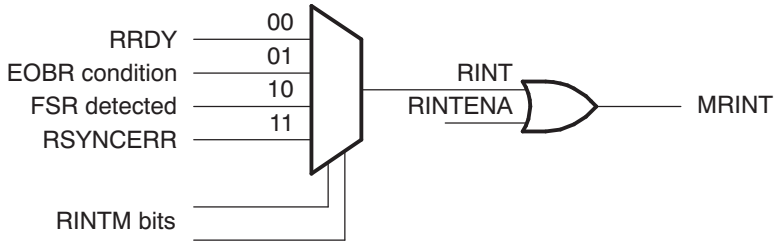


Table 34-72. Receive Interrupt Sources and Signals

McBSP Interrupt Signal	Interrupt Flags	Interrupt Enables in SPCR1	Interrupt Enables	Type of Interrupt	Interrupt Line
		RINTM Bits			
RINT	RRDY	0	RINTENA	Every word receive	MRINT
	EOBR	1	RINTENA	Every 16 channel block boundary	
	FSR	10	RINTENA	On every FSR	
	RSYNCERR	11	RINTENA	Frame sync error	

NOTE: Since X/RINT, X/REVTA, and X/RXFFINT share the same CPU interrupt, it is recommended that all applications use one of the above selections for interrupt generation. If multiple interrupt enables are selected at the same time, there is a likelihood of interrupts being masked or not recognized.

34.12.2 McBSP Transmit Interrupt Generation

McBSP module data transmit and error conditions generate two sets of interrupt signals. One set is used for the CPU and the other set is for DMA.

Figure 34-66. Transmit Interrupt Generation

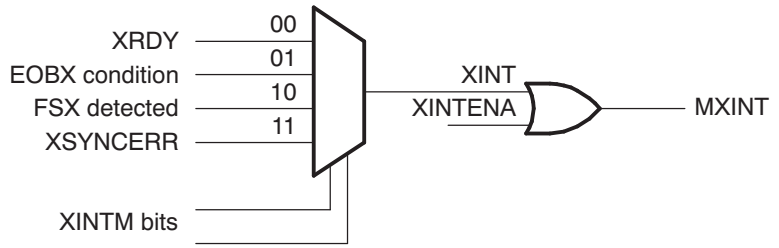

Table 34-73. Transmit Interrupt Sources and Signals

McBSP Interrupt Signal	Interrupt Flags	Interrupt Enables in SPCR2	Interrupt Enables	Type of Interrupt	Interrupt Line
		XINTM Bits			
XINT	XRDY	0	XINTENA	Every word transmit	MXINT
	EOBX	1	XINTENA	Every 16-channel block boundary	

Table 34-73. Transmit Interrupt Sources and Signals (continued)

McBSP Interrupt Signal	Interrupt Flags	Interrupt Enables in SPCR2	Interrupt Enables	Type of Interrupt	Interrupt Line
	FSX	10	XINTENA	On every FSX	
	XSYNCERR	11	XINTENA	Frame sync error	

34.12.3 Error Flags

The McBSP has several error flags both on receive and transmit channel. Table 34-74 explains the error flags and their meaning.

Table 34-74. Error Flags

Error Flags	Function
RFULL	Indicates DRR2/DRR1 are not read and RXR register is overwritten
RSYNCERR	Indicates unexpected frame-sync condition, current data reception will abort and restart. Use RINTM bit 11 for interrupt generation on this condition.
XSYNCERR	Indicates unexpected frame-sync condition, current data transmission will abort and restart. Use XINTM bit 11 for interrupt generation on this condition.

34.13 McBSP Modes

McBSP, in its normal mode, communicates with various types of Codecs with variable word size. Apart from this mode, the McBSP uses time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices. The multichannel mode provides flexibility while transmitting/receiving selected channels or all the channels in a TDM stream.

Table 34-75 provides a quick reference to McBSP mode selection.

Table 34-75. McBSP Mode Selection

		Register Bits Used for Mode Selection				
		MCR1 bit 9,0		MCR2 bit 9,1,0		
No.	McBSP Word Size	RMCME	RMCM	XMCME	XMCM	Mode and Function Description
						Normal Mode
1	8/12/16/20/24/32 bit words	0	0	0	0	All types of Codec interface will use this selection
						Multichannel Mode
2	8-bit words					2 Partition or 32-channel Mode
		0	1	0	1	All channels are disabled,unless selected in X/RCERA/B
		0	1	0	10	All channels are enabled,but masked unless selected in X/RCERA/B
		0	1	0	11	Symmetric transmit, receive 8 Partition or 128 Channel Mode Transmit/ Receive Channels selected by X/RCERA to X/RCERH bits
						Multichannel Mode is ON
		1	1	1	1	All channels are disabled,unless selected in XCERs
		1	1	1	10	All channels are enabled,but masked unless

Table 34-75. McBSP Mode Selection (continued)

No.	McBSP Word Size	Register Bits Used for Mode Selection				Mode and Function Description
		MCR1 bit 9,0		MCR2 bit 9,1,0		
		RMCME	RMCM	XMCME	XMCM	
						selected in XCERs
		1	1	1	11	Symmetric transmit, receive
						Continuous Mode - Transmit
		1	0	1	0	**Multi-Channel Mode is OFF**
						All 128 channels are active and enabled

34.14 Special Case: External Device is the Transmit Frame Master

Care must be taken if the transmitter expects a frame sync from an external device. After the transmitter comes out of reset (XRST = 1), it waits for a frame sync from the external device. If the first frame sync arrives very shortly after the transmitter is enabled, the CPU or DMA controller may not have a chance to service DXR. In this case, the transmitter shifts out the default data in XSR instead of the desired value, which has not yet arrived in DXR. This causes problems in some applications, as the first data element in the frame is invalid. The data stream appears element-shifted (the first data word may appear in the second channel instead of the first).

To ensure proper operation when the external device is the frame master, you must assure that DXR is already serviced with the first word when a frame sync occurs. To do so, you can keep the transmitter in reset until the first frame sync is detected. Upon detection of the first frame sync, the McBSP generates an interrupt to the CPU. Within the interrupt service routine, the transmitter is taken out of reset (XRST = 1). This assures that the transmitter does not begin data transfers at the data pin during the first frame sync period. This also provides almost an entire frame period for the DSP to service DXR with the first word before the second frame sync occurs. The transmitter only begins data transfers upon receiving the second frame sync. At this point, DXR is already serviced with the first word.

The interrupt service routine must first be setup according to the description in . Then follow this modified procedure for proper initialization:

1. Ensure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0). The respective portion of the McBSP needs to be in reset (XRST = 0 and/or RRST = 0).
2. Program SRGR and other control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0). Also ensure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRST = 0).
3. Program the XINTM bits to 2h in SPCR to generate an interrupt to the CPU upon detection of a transmit frame sync. Do not enable the XINT interrupt in the interrupt enable register (IER) in this step.
4. Wait for proper internal synchronization. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the McBSP is the bit clock master and the internal sample rate generator is used.
   a. Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
   b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to 1/(CLKGDV + 1) of the sample rate generator source clock CLKSRG.
6. A transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
   a. Set the XRST bit to 1 to enable the transmitter.
   b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock,

wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.

c. Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.

7. Setup data acquisition as required:
   a. If the DMA controller is used to service the McBSP, setup data acquisition as desired and start the DMA controller in this step, before the McBSP is taken out of reset.
   b. If CPU interrupt is used to service the McBSP, no action is required in this step.
   c. If CPU polling is used to service the McBSP, no action is required in this step.
8. Enable the XINT interrupt by setting the corresponding bit in the interrupt enable register (IER). In this step, the McBSP transmitter is still in reset. Upon detection of the first transmit frame sync from the external device, the McBSP generates an interrupt to the CPU and the DSP enters the interrupt service routine (ISR). The ISR needs to perform these tasks in this order:
   a. Modify the XINTM bits to the value desired for normal McBSP operations. If CPU interrupt is used to service the McBSP in normal operations, ensure that the XINTM bits are modified to 0 to detect the McBSP XRDY event. If no McBSP interrupt is desired in normal operations, disable future McBSP-to-CPU interrupt in the interrupt enable register (IER).
   b. Set the XRST bit and/or the RRST bit to 1 to enable the respective portion of the McBSP. The McBSP is now ready to transmit and/or receive.
9. Service the McBSP:
   a. If CPU polling is used to service the McBSP in normal operations, it can do so upon exit from the ISR.
   b. If CPU interrupt is used to service the McBSP in normal operations, upon XRDY interrupt service routine is entered. The ISR should be setup to verify that XRDY = 1 and service the McBSP accordingly.
   c. If DMA controller is used to service the McBSP in normal operations, it services the McBSP automatically upon receiving the XEVT and/or REVT.
10. Upon detection of the second frame sync, DXR is already serviced and the transmitter is ready to transmit the valid data. The receiver is also serviced properly by the DSP.

34.15 McBSP Registers

This section describes the McBSP registers.

34.15.1 McBSP Base Addresses

Table 34-76. MCBSP Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
McbspaRegs	MCBSP_REGS	MCBSPA_BASE	0x0000_6000	YES	YES	YES	YES	YES
McbspbRegs	MCBSP_REGS	MCBSPB_BASE	0x0000_6040	YES	YES	YES	YES	YES

Table 34-77 shows the registers accessible on each McBSP. Section 34.15.2 through Section 34.15.11 describe the register bits.

Table 34-77. McBSP Register Summary

Name	McBSP-A Address	McBSP-B Address	Type	Reset Value	Description
Data Registers, Receive, Transmit					
DRR2	0x6000	0x6040	R	0x0000	McBSP Data Receive Register 2
DRR1	0x6001	0x6041	R	0x0000	McBSP Data Receive Register 1
DXR2	0x6002	0x6042	W	0x0000	McBSP Data Transmit Register 2
DXR1	0x6003	0x6043	W	0x0000	McBSP Data Transmit Register 1

MFFINT	0x6023	0x6063	R/W	0x0000	McBSP Interrupt Enable Register

34.15.2 Data Receive Registers (DRR[1,2])

The CPU or the DMA controller reads received data from one or both of the data receive registers (see Figure 34-67). If the serial word length is 16 bits or smaller, only DRR1 is used. If the serial length is larger than 16 bits, both DRR1 and DRR2 are used and DRR2 holds the most significant bits. Each frame of receive data in the McBSP can have one phase or two phases, each with its own serial word length.

Figure 34-67. Data Receive Registers (DRR2 and DRR1)

DDR2

15	0
High part of receive data (for 20-, 24- or 32-bit data)	
R/W-0	

DDR1

15	0
Receive data (for 8-, 12-, or 16-bit data) or low part of receive data (for 20-, 24- or 32-bit data)	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

34.15.2.1 Data Travel From Data Receive Pins to the Registers

If the serial word length is 16 bits or smaller, receive data on the MDRx pin is shifted into receive shift register 1 (RSR1) and then copied into receive buffer register 1 (RBR1). The content of RBR1 is then copied to DRR1, which can be read by the CPU or by the DMA controller. The RSRs and RBRs are not accessible to the user.

If the serial word length is larger than 16 bits, receive data on the MDRx pin is shifted into both of the receive shift registers (RSR2, RSR1) and then copied into both of the receive buffer registers (RBR2, RBR1). The content of the RBRs is then copied into both of the DRRs, which can be read by the CPU or by the DMA controller.

If companding is used during the copy from RBR1 to DRR1 (RCOMPAND = 10b or 11b), the 8-bit compressed data in RBR1 is expanded to a left-justified 16-bit value in DRR1. If companding is disabled, the data copied from RBR[1,2] to DRR[1,2] is justified and bit filled according to the RJUST bits.

34.15.3 Data Transmit Registers (DXR[1,2])

For transmission, the CPU or the DMA controller writes data to one or both of the data transmit registers (see Figure 34-68). If the serial word length is 16 bits or smaller, only DXR1 is used. If the word length is larger than 16 bits, both DXR1 and DXR2 are used and DXR2 holds the most significant bits. Each frame of transmit data in the McBSP can have one phase or two phases, each with its own serial word length.

Figure 34-68. Data Transmit Registers (DXR2 and DXR1)

DXR2

15	0
High part of transmit data (for 20-, 24- or 32-bit data)	
R/W-0	

DXR1

15	0
Transmit data (for 8-, 12-, or 16-bit data) or low part of receive data (for 20-, 24- or 32-bit data)	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

34.15.3.1 Data Travel From Registers to Data Transmit (DX) Pins

If the serial word length is 16 bits or fewer, data written to DXR1 is copied to transmit shift register 1 (XSR1). From XSR1, the data is shifted onto the DX pin one bit at a time. The XSRs are not accessible.

If the serial word length is more than 16 bits, data written to DXR1 and DXR2 is copied to both transmit shift registers (XSR2, XSR1). From the XSRs, the data is shifted onto the DX pin one bit at a time.

If companding is used during the transfer from DXR1 to XSR1 (XCOMPAND = 10b or 11b), the McBSP compresses the 16-bit data in DXR1 to 8-bit data in the μ-law or A-law format in XSR1. If companding is disabled, the McBSP passes data from the DXR(s) to the XSR(s) without modification.

34.15.4 Serial Port Control Registers (SPCR[1,2])

Each McBSP has two serial port control registers, SPCR1 (Table 34-78) and SPCR2 (Table 34-79). These registers enable you to:

- Control various McBSP modes: digital loopback mode (DLB), sign-extension and justification mode for reception (RJUST), clock stop mode (CLKSTP), interrupt modes (RINTM and XINTM), emulation mode (FREE and SOFT)
- Turn on and off the DX-pin delay enabler (DXENA)
- Check the status of receive and transmit operations (RSYNCERR, XSYNCERR, RFULL, XEMPTY, RRDY, XRDY)
- Reset portions of the McBSP (RRST, XRST, FRST, GRST)

34.15.4.1 Serial Port Control 1 Register (SPCR1)

The serial port control 1 register (SPCR1) is shown in Figure 34-69 and described in Table 34-78.

Figure 34-69. Serial Port Control 1 Register (SPCR1)

15	14	13	12	11	10	9	8
DLB	RJUST		CLKSTP		Reserved		
R/W-0	R/W-0		R/W-0		R-0		

7	6	5	4	3	2	1	0
DXENA	Reserved	RINTM		RSYNCERR	RFULL	RRDY	RRST
R/W-0	R/W-0	R/W-0		R/W-0	R-0	R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 34-78. Serial Port Control 1 Register (SPCR1) Field Descriptions

Bit	Field	Value	Description
15	DLB		Digital loopback mode bit. DLB disables or enables the digital loopback mode of the McBSP:
		0	Disabled
			Internal DR is supplied by the MDRx pin. Internal FSR and internal MCLKR can be supplied by their respective pins or by the sample rate generator, depending on the mode bits FSRM and CLKRM.
			Internal DX is supplied by the MDXx pin. Internal FSX and internal CLKX are supplied by their respective pins or are generated internally, depending on the mode bits FSXM and CLKXM.
		1	Enabled
			Internal receive signals are supplied by internal transmit signals:
			MDRx connected to MDXx
			MFSRx connected to MFSXx
			MCLKR connected to MCLKXx
			This mode allows you to test serial port code with a single DSP. The McBSP transmitter directly supplies data, frame synchronization, and clocking to the McBSP receiver.
14-13	RJUST	0-3h	Receive sign-extension and justification mode bits. During reception, RJUST determines how data is justified and bit filled before being passed to the data receive registers (DRR1, DRR2).
			RJUST is ignored if you enable a companding mode with the RCOMPAND bits. In a companding mode, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1.
			For more details about the effects of RJUST, see Section 34.8.13.
		0	Right justify the data and zero fill the MSBs.
		1h	Right justify the data and sign-extend the data into the MSBs.
		2h	Left justify the data and zero fill the LSBs.
		3h	Reserved (do not use)
12-11	CLKSTP	0-3h	Clock stop mode bits. CLKSTP allows you to use the clock stop mode to support the SPI master-slave protocol. If you will not be using the SPI protocol, you can clear CLKSTP to disable the clock stop mode.
			In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b).
			For more details, see Section 34.8.5.
		0-1h	Clock stop mode is disabled.
		2h	Clock stop mode, without clock delay
		3h	Clock stop mode, with half-cycle clock delay
10-8	Reserved	0	Reserved bits (not available for your use). They are read-only bits and return 0s when read.
7	DXENA		DX delay enabler mode bit. DXENA controls the delay enabler for the DX pin. The enabler creates an extra delay for turn-on time (for the length of the delay, see the device-specific data sheet). For more details about the effects of DXENA, see Section 34.9.14.
		0	DX delay enabler off
		1	DX delay enabler on
6	Reserved	0	Reserved

Table 34-78. Serial Port Control 1 Register (SPCR1) Field Descriptions (continued)

Bit	Field	Value	Description
5-4	RINTM	0-3h	Receive interrupt mode bits. RINTM determines which event in the McBSP receiver generates a receive interrupt (RINT) request. If RINT is properly enabled inside the CPU, the CPU services the interrupt request; otherwise, the CPU ignores the request.
		0	The McBSP sends a receive interrupt (RINT) request to the CPU when the RRDY bit changes from 0 to 1, indicating that receive data is ready to be read (the content of RBR[1,2] has been copied to DRR[1,2]): Regardless of the value of RINTM, you can check RRDY to determine whether a word transfer is complete. The McBSP sends a RINT request to the CPU when 16 enabled bits have been received on the DR pin.
		1h	In the multichannel selection mode, the McBSP sends a RINT request to the CPU after every 16-channel block is received in a frame. Outside of the multichannel selection mode, no interrupt request is sent.
		2h	The McBSP sends a RINT request to the CPU when each receive frame-synchronization pulse is detected. The interrupt request is sent even if the receiver is in its reset state.
		3h	The McBSP sends a RINT request to the CPU when the RSYNCERR bit is set, indicating a receive frame-synchronization error. Regardless of the value of RINTM, you can check RSYNCERR to determine whether a receive frame-synchronization error occurred.
3	RSYNCERR		Receive frame-sync error bit. RSYNCERR is set when a receive frame-sync error is detected by the McBSP. If RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU when RSYNCERR is set. The flag remains set until you write a 0 to it or reset the receiver.
		0	No error
		1	Receive frame-synchronization error. For more details about this error, see Section 34.5.3.
2	RFULL		Receiver full bit. RFULL is set when the receiver is full with new data and the previously received data has not been read (receiver-full condition). For more details about this condition, see Section 34.5.2.
		0	No receiver-full condition
		1	Receiver-full condition: RSR[1,2] and RBR[1,2] are full with new data, but the previous data in DRR[1,2] has not been read.
1	RRDY		Receiver ready bit. RRDY is set when data is ready to be read from DRR[1,2]. Specifically, RRDY is set in response to a copy from RBR1 to DRR1. If the receive interrupt mode is RINTM = 00b, the McBSP sends a receive interrupt request to the CPU when RRDY changes from 0 to 1. Also, when RRDY changes from 0 to 1, the McBSP sends a receive synchronization event (REVT) signal to the DMA controller.
		0	Receiver not ready When the content of DRR1 is read, RRDY is automatically cleared.
		1	Receiver ready: New data can be read from DRR[1,2]. Important: If both DRRs are required (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.
0	RRST		Receiver reset bit. You can use RRST to take the McBSP receiver into and out of its reset state. This bit has a negative polarity; RRST = 0 indicates the reset state. To read about the effects of a receiver reset, see Section 34.10.2.
		0	If you read a 0, the receiver is in its reset state. If you write a 0, you reset the receiver.
		1	If you read a 1, the receiver is enabled. If you write a 1, you enable the receiver by taking it out of its reset state.

34.15.4.2 Serial Port Control 2 Register (SPCR2)

The serial port control 2 register (SPCR2) is shown in Figure 34-70 and described in Table 34-79.

Figure 34-70. Serial Port Control 2 Register (SPCR2)

15						10	9	8
Reserved							FREE	SOFT
R-0							R/W-0	R/W-0
7	6	5	4	3	2	1	0	
FRST	GRST	XINTM		XSYNCERR	XEMPTY	XRDY	XRST	
R/W-0	R/W-0	R/W-0		R/W-0	R-0	R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 34-79. Serial Port Control 2 Register (SPCR2) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reserved bits (not available for your use). They are read-only bits and return 0s when read.
9	FREE		Free run bit. When a breakpoint is encountered in the high-level language debugger, FREE determines whether the McBSP transmit and receive clocks continue to run or whether they are affected as determined by the SOFT bit. When one of the clocks stops, the corresponding data transfer (transmission or reception) stops.
8	SOFT		Soft stop bit. When FREE = 0, SOFT determines the response of the McBSP transmit and receive clocks when a breakpoint is encountered in the high-level language debugger. When one of the clocks stops, the corresponding data transfer (transmission or reception) stops.
7	FRST		Frame-synchronization logic reset bit. The sample rate generator of the McBSP includes frame-synchronization logic to generate an internal frame-synchronization signal. You can use FRST to take the frame-synchronization logic into and out of its reset state. This bit has a negative polarity; FRST = 0 indicates the reset state.
		0	If you read a 0, the frame-synchronization logic is in its reset state.
			If you write a 0, you reset the frame-synchronization logic.
			In the reset state, the frame-synchronization logic does not generate a frame-synchronization signal (FSG).
		1	If you read a 1, the frame-synchronization logic is enabled.
			If you write a 1, you enable the frame-synchronization logic by taking it out of its reset state.
			When the frame-synchronization logic is enabled (FRST = 1) and the sample rate generator as a whole is enabled (GRST = 1), the frame-synchronization logic generates the frame-synchronization signal FSG as programmed.
6	GRST		Sample rate generator reset bit. You can use GRST to take the McBSP sample rate generator into and out of its reset state. This bit has a negative polarity; GRST = 0 indicates the reset state.
			To read about the effects of a sample rate generator reset, see Section 34.10.2.
		0	If you read a 0, the sample rate generator is in its reset state.
			If you write a 0, you reset the sample rate generator.
			If GRST = 0 due to a reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive).
		1	If you read a 1, the sample rate generator is enabled.
			If you write a 1, you enable the sample rate generator by taking it out of its reset state.
			When enabled, the sample rate generator generates the clock signal CLKG as programmed in the sample rate generator registers. If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers.

Table 34-79. Serial Port Control 2 Register (SPCR2) Field Descriptions (continued)

Bit	Field	Value	Description
5-4	XINTM	0-3h	Transmit interrupt mode bits. XINTM determines which event in the McBSP transmitter generates a transmit interrupt (XINT) request. If XINT is properly enabled, the CPU services the interrupt request; otherwise, the CPU ignores the request.
		0	The McBSP sends a transmit interrupt (XINT) request to the CPU when the XRDY bit changes from 0 to 1, indicating that transmitter is ready to accept new data (the content of DXR[1,2] has been copied to XSR[1,2]). Regardless of the value of XINTM, you can check XRDY to determine whether a word transfer is complete.
		1h	The McBSP sends an XINT request to the CPU when 16 enabled bits have been transmitted on the DX pin. In the multichannel selection mode, the McBSP sends an XINT request to the CPU after every 16-channel block is transmitted in a frame. Outside of the multichannel selection mode, no interrupt request is sent.
		2h	The McBSP sends an XINT request to the CPU when each transmit frame-synchronization pulse is detected. The interrupt request is sent even if the transmitter is in its reset state.
		3h	The McBSP sends an XINT request to the CPU when the XSYNCERR bit is set, indicating a transmit frame-synchronization error. Regardless of the value of XINTM, you can check XSYNCERR to determine whether a transmit frame-synchronization error occurred.
3	XSYNCERR		Transmit frame-synchronization error bit. XSYNCERR is set when a transmit frame-synchronization error is detected by the McBSP. If XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU when XSYNCERR is set. The flag remains set until you write a 0 to it or reset the transmitter. If XINTM = 11b, writing a 1 to XSYNCERR triggers a transmit interrupt just as if a transmit frame-synchronization error occurred. For details about this error see Section 34.5.6.
		0	No error
		1	Transmit frame-synchronization error
2	XEMPTY		Transmitter empty bit. XEMPTY is cleared when the transmitter is ready to send new data but no new data is available (transmitter-empty condition). This bit has a negative polarity; a transmitter-empty condition is indicated by XEMPTY = 0.
		0	Transmitter-empty condition Typically this indicates that all the bits of the current word have been transmitted but there is no new data in DXR1. XEMPTY is also cleared if the transmitter is reset and then restarted. For more details about this error condition, see Section 34.5.5.
		1	No transmitter-empty condition
1	XRDY		Transmitter ready bit. XRDY is set when the transmitter is ready to accept new data in DXR[1,2]. Specifically, XRDY is set in response to a copy from DXR1 to XSR1. If the transmit interrupt mode is XINTM = 00b, the McBSP sends a transmit interrupt (XINT) request to the CPU when XRDY changes from 0 to 1. Also, when XRDY changes from 0 to 1, the McBSP sends a transmit synchronization event (XEVT) signal to the DMA controller.
		0	Transmitter not ready When DXR1 is loaded, XRDY is automatically cleared.
		1	Transmitter ready: DXR[1,2] is ready to accept new data. If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs), as described in the next step. If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

Table 34-79. Serial Port Control 2 Register (SPCR2) Field Descriptions (continued)

Bit	Field	Value	Description
0	XRST		Transmitter reset bit. You can use XRST to take the McBSP transmitter into and out of its reset state. This bit has a negative polarity; XRST = 0 indicates the reset state.
			To read about the effects of a transmitter reset, see Section 34.10.2.
		0	If you read a 0, the transmitter is in its reset state.
			If you write a 0, you reset the transmitter.
		1	If you read a 1, the transmitter is enabled.
			If you write a 1, you enable the transmitter by taking it out of its reset state.

34.15.5 Receive Control Registers (RCR[1, 2])

Each McBSP has two receive control registers, RCR1 (Table 34-80) and RCR2 (Table 34-82). These registers enable you to:

- Specify one or two phases for each frame of receive data (RPHASE)
- Define two parameters for phase 1 and (if necessary) phase 2: the serial word length (RWDLEN1, RWDLEN2) and the number of words (RFRLEN1, RFRLEN2)
- Choose a receive companding mode, if any (RCOMPAND)
- Enable or disable the receive frame-synchronization ignore function (RFIG)
- Choose a receive data delay (RDATDLY)

34.15.5.1 Receive Control Register 1 (RCR1)

The receive control register 1 (RCR1) is shown in Figure 34-71 and described in Table 34-80.

Figure 34-71. Receive Control Register 1 (RCR1)

Table 34-80. Receive Control Register 1 (RCR1) Field Descriptions

Bit	Field	Value	Description
15	Reserved	0	Reserved bits (not available for your use). They are read-only bits and return 0s when read.
14-8	RFRLEN1	0-7Fh	Receive frame length 1 (1 to 128 words). Each frame of receive data can have one or two phases, depending on value that you load into the RPHASE bit. If a single-phase frame is selected, RFRLEN1 in RCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dual-phase frame is selected, RFRLEN1 determines the number of serial words in phase 1 of the frame, and RFRLEN2 in RCR2 determines the number of words in phase 2 of the frame. The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 34-81 for a summary of how you determine the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization period. Program the RFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into RFRLEN1.

Table 34-80. Receive Control Register 1 (RCR1) Field Descriptions (continued)

Bit	Field	Value	Description
7-5	RWDLEN1	0-7h	Receive word length 1. Each frame of receive data can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 in RCR1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame, and RWDLEN2 in RCR2 determines the word length in phase 2 of the frame.

Table 34-82. Receive Control Register 2 (RCR2) Field Descriptions

Bit	Field	Value	Description
15	RPHASE		Receive phase number bit. RPHASE determines whether the receive frame has one phase or two phases. For each phase you can define the serial word length and the number of serial words in the phase. To set up phase 1, program RWDLEN1 (word length) and RFRLEN1 (number of words). To set up phase 2 (if there are two phases), program RWDLEN2 and RFRLEN2.
		0	Single-phase frame
			The receive frame has only one phase, phase 1.
		1	Dual-phase frame
			The receive frame has two phases, phase 1 and phase 2.
14-8		0-7Fh	Receive frame length 2 (1 to 128 words). Each frame of receive data can have one or two phases, depending on value that you load into the RPHASE bit. If a single-phase frame is selected, RFRLEN1 in RCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dual-phase frame is selected, RFRLEN1 determines the number of serial words in phase 1 of the frame, and RFRLEN2 in RCR2 determines the number of words in phase 2 of the frame. The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 34-83 for a summary of how to determine the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization period.
			Program the RFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For example, if you want a phase length of 128 words in phase 2, load 127 into RFRLEN2.

Table 34-82. Receive Control Register 2 (RCR2) Field Descriptions (continued)

Bit	Field	Value	Description
7-5	RWDLEN2	0-7h	Receive word length 2. Each frame of receive data can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 in RCR1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame, and RWDLEN2 in RCR2 determines the word length in phase 2 of the frame.
		0	8 bits
		1h	12 bits
		2h	16 bits
		3h	20 bits
		4h	24 bits
		5h	32 bits
		6h-7h	Reserved (do not use)
4-3	RCOMPAND	0-3h	Receive companding mode bits. Companding (COMpress and exPAND) hardware allows compression and expansion of data in either μ-law or A-law format. RCOMPAND allows you to choose one of the following companding modes for the McBSP receiver: For more details about these companding modes, see Section 34.3.2.
		0	No companding, any size data, MSB received first
		1h	No companding, 8-bit data, LSB received first
		2h	μ-law companding, 8-bit data, MSB received first
		3h	A-law companding, 8-bit data, MSB received first
2	RFIG		Receive frame-synchronization ignore bit. If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse. For more details about the frame-synchronization error condition, see Figure 34-30. Setting RFIG causes the serial port to ignore unexpected frame-synchronization signals during reception. For more details on the effects of RFIG, see Section 34.8.10.1.
		0	Frame-synchronization detect. An unexpected FSR pulse causes the receiver to discard the contents of RSR[1,2] in favor of the new incoming data. The receiver: 1. Aborts the current data transfer 2. Sets RSYNCERR in SPCR1 3. Begins the transfer of a new data word
		1	Frame-synchronization ignore. An unexpected FSR pulse is ignored. Reception continues uninterrupted.
1-0	RDATDLY	0-3h	Receive data delay bits. RDATDLY specifies a data delay of 0, 1, or 2 receive clock cycles after frame-synchronization and before the reception of the first bit of the frame. For more details, see Section 34.8.12.
		0	0-bit data delay
		1h	1-bit data delay
		2h	2-bit data delay
		3h	Reserved (do not use)

Table 34-83. Frame Length Formula for Receive Control 2 Register (RCR2)

RPHASE	RFRLEN1	RFRLEN2	Frame Length
0	0 ≤ RFRLEN1 ≤ 127	Not used	(RFRLEN1 + 1) words
1	0 ≤ RFRLEN1 ≤ 127	0 ≤ RFRLEN2 ≤ 127	(RFRLEN1 + 1) + (RFRLEN2 + 1) words

34.15.6 Transmit Control Registers (XCR1 and XCR2)

Each McBSP has two transmit control registers, XCR1 (Table 34-84) and XCR2 (Table 34-86). These registers enable you to:

- Specify one or two phases for each frame of transmit data (XPHASE)
- Define two parameters for phase 1 and (if necessary) phase 2: the serial word length (XWDLEN1,

XWDLEN2) and the number of words (XFRLEN1, XFRLEN2)

- Choose a transmit companding mode, if any (XCOMPAND)
- Enable or disable the transmit frame-sync ignore function (XFIG)
- Choose a transmit data delay (XDATDLY)

34.15.6.1 Transmit Control 1 Register (XCR1)

The transmit control 1 register (XCR1) is shown in Figure 34-73 and described in Table 34-84.

Table 34-84. Transmit Control 1 Register (XCR1) Field Descriptions

Bit	Field	Value	Description
15	Reserved	0	Reserved bit. Read-only; returns 0 when read.
14-8	XFRLEN1	0-7Fh	Transmit frame length 1 (1 to 128 words). Each frame of transmit data can have one or two phases, depending on value that you load into the XPHASE bit. If a single-phase frame is selected, XFRLEN1 in XCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dual-phase frame is selected, XFRLEN1 determines the number of serial words in phase 1 of the frame and XFRLEN2 in XCR2 determines the number of words in phase 2 of the frame. The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 34-85 for a summary of how you determine the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization period. Program the XFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.
7-5	XWDLEN1	0-3h	Transmit word length 1. Each frame of transmit data can have one or two phases, depending on the value that you load into the XPHASE bit. If a single-phase frame is selected, XWDLEN1 in XCR1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame and XWDLEN2 in XCR2 determines the word length in phase 2 of the frame.
		0	8 bits
		1h	12 bits
		2h	16 bits
		3h	20 bits
		4h	24 bits
		5h	32 bits
		6h-7h	Reserved (do not use)
4-0	Reserved	0	Reserved bits. They are read-only bits and return 0s when read.

Table 34-85. Frame Length Formula for Transmit Control 1 Register (XCR1)

Table 34-86. Transmit Control 2 Register (XCR2) Field Descriptions

Bit	Field	Value	Description
15	XPHASE		Transmit phase number bit. XPHASE determines whether the transmit frame has one phase or two phases. For each phase you can define the serial word length and the number of serial words in the phase. To set up phase 1, program XWDLEN1 (word length) and XFRLEN1 (number of words). To set up phase 2 (if there are two phases), program XWDLEN2 and XFRLEN2.
		0	Single-phase frame
			The transmit frame has only one phase, phase 1.
		1	Dual-phase frame
			The transmit frame has two phases, phase 1 and phase 2.
14-8	XFRLEN2	0-7Fh	Transmit frame length 2 (1 to 128 words). Each frame of transmit data can have one or two phases, depending on value that you load into the XPHASE bit. If a single-phase frame is selected, XFRLEN1 in XCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dual-phase frame is selected, XFRLEN1 determines the number of serial words in phase 1 of the frame and XFRLEN2 in XCR2 determines the number of words in phase 2 of the frame. The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 34-87 for a summary of how to determine the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization period.
			Program the XFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.
7-5	XWDLEN2	0-7h	Transmit word length 2. Each frame of transmit data can have one or two phases, depending on the value that you load into the XPHASE bit. If a single-phase frame is selected, XWDLEN1 in XCR1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame and XWDLEN2 in XCR2 determines the word length in phase 2 of the frame.
		0	8 bits
		1h	12 bits
		2h	16 bits
		3h	20 bits
		4h	24 bits
		5h	32 bits
		6h-7h	Reserved (do not use)
4-3	XCOMPAND	0-3h	Transmit companding mode bits. Companding (COMpress and exPAND) hardware allows compression and expansion of data in either μ-law or A-law format. For more details, see Section 34.3.2.
			XCOMPAND allows you to choose one of the following companding modes for the McBSP transmitter. For more details about these companding modes, see Section 34.3.2.
		0	No companding, any size data, MSB transmitted first
		1h	No companding, 8-bit data, LSB transmitted first
		2h	μ-law companding, 8-bit data, MSB transmitted first
		3h	A-law companding, 8-bit data, MSB transmitted first

Table 34-86. Transmit Control 2 Register (XCR2) Field Descriptions (continued)

Bit	Field	Value	Description
2	XFIG		Transmit frame-synchronization ignore bit. If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse. Setting XFIG causes the serial port to ignore unexpected frame-synchronization pulses during transmission.
		0	Frame-synchronization detect. An unexpected FSX pulse causes the transmitter to discard the content of XSR[1,2]. The transmitter: 1. Aborts the present transmission 2. Sets XSYNCERR in SPCR2 3. Begins a new transmission from DXR[1,2]. If new data was written to DXR[1,2] since the last DXR[1,2]-to-XSR[1,2] copy, the current value in XSR[1,2] is lost. Otherwise, the same data is transmitted.
		1	Frame-synchronization ignore. An unexpected FSX pulse is ignored. Transmission continues uninterrupted.
1-0	XDATDLY	0-3h	Transmit data delay bits. XDATDLY specifies a data delay of 0, 1, or 2 transmit clock cycles after frame synchronization and before the transmission of the first bit of the frame. For more details, see Section 34.9.13.
		0	0-bit data delay
		1h	1-bit data delay
		2h	2-bit data delay
		3h	Reserved (do not use)

Table 34-87. Frame Length Formula for Transmit Control 2 Register (XCR2)

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	0 ≤ XFRLEN1 ≤ 127	Not used	(XFRLEN1 + 1) words
1	0 ≤ XFRLEN1 ≤ 127	0 ≤ XFRLEN2 ≤ 127	(XFRLEN1 + 1) + (XFRLEN2 + 1) words

34.15.7 Sample Rate Generator Registers (SRGR1 and SRGR2)

Each McBSP has two sample rate generator registers, SRGR1 (Table 34-88) and SRGR2 (Table 34-89). The sample rate generator can generate a clock signal (CLKG) and a frame-synchronization signal (FSG). The registers SRGR1 and SRGR2 enable you to:

- Select the input clock source for the sample rate generator (CLKSM, in conjunction with the SCLKME bit of PCR)
- Divide down the frequency of CLKG (CLKGDV)
- Select whether internally-generated transmit frame-synchronization pulses are driven by FSG or by activity in the transmitter (FSGM).
- Specify the width of frame-synchronization pulses on FSG (FWID) and specify the period between those pulses (FPER)

When an external source (via the MCLKR or MCLKX pin) provides the input clock source for the sample rate generator:

- If the CLKX/MCLKR pin is used, the polarity of the input clock is selected with CLKXP/CLKRP of PCR.
- The GSYNC bit of SRGR2 allows you to make CLKG synchronized to an external frame-synchronization signal on the FSR pin, so that CLKG is kept in phase with the input clock.

34.15.7.1 Sample Rate Generator 1 Register (SRGR1)

The sample rate generator 1 register is shown in Figure 34-75 and described in Table 34-88.

Figure 34-75. Sample Rate Generator 1 Register (SRGR1)

15							8
FWID							
R/W-0							
7							0
CLKGDV							
R/W-1							

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 34-88. Sample Rate Generator 1 Register (SRGR1) Field Descriptions

Bit	Field	Value	Description
15-8	FWID	0-FFh	Frame-synchronization pulse width bits for FSG The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. For frame-synchronization pulses on FSG, (FWID + 1) is the pulse width in CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles: 0 ≤ FWID ≤ 255 1 ≤ (FWID + 1) ≤ 256 CLKG cycles The period between the frame-synchronization pulses on FSG is defined by the FPER bits.
7-0	CLKGDV	0-FFh	Divide-down value for CLKG. The sample rate generator can accept an input clock signal and divide it down according to CLKGDV to produce an output clock signal, CLKG. The frequency of CLKG is: CLKG frequency = (Input clock frequency)/ (CLKGDV + 1) The input clock is selected by the SCLKME and CLKSM bits: **SCLKME** / **CLKSM** / **Input Clock For Sample Rate Generator** 0 / 0 / Reserved 0 / 1 / LSPCLK 1 / 0 / Signal on MCLKR pin 1 / 1 / Signal on MCLKX pin

34.15.7.2 Sample Rate Generator 2 Register (SRGR2)

The sample rate generator 2 register (SRGR2) is shown in Figure 34-76 and described in Table 34-89.

Figure 34-76. Sample Rate Generator 2 Register (SRGR2)

15	14	13	12	11			8
GSYNC	Reserved	CLKSM	FSGM	FPER			
R/W-0	R/W-0	R/W-1	R/W-0	R/W-0			
7							0
FPER							
R/W-0							

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 34-89. Sample Rate Generator 2 Register (SRGR2) Field Descriptions

Bit	Field	Value	Description
15	GSYNC		Clock synchronization mode bit for CLKG. GSYNC is used only when the input clock source for the sample rate generator is external—on the MCLKR pin. When GSYNC = 1, the clock signal (CLKG) and the frame-synchronization signal (FSG) generated by the sample rate generator are made dependent on pulses on the FSR pin.
		0	No clock synchronization CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles.
		1	Clock synchronization • CLKG is adjusted as necessary so that it is synchronized with the input clock on the MCLKR pin. • FSG pulses. FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored. For more details, see Section 34.4.3.
14	Reserved		Reserved
13	CLKSM	0	Sample rate generator input clock mode bit. The sample rate generator can accept an input clock signal and divide it down according to CLKGDV to produce an output clock signal, CLKG. The frequency of CLKG is:) CLKG frequency = (input clock frequency)/ (CLKGDV + 1 CLKSM is used in conjunction with the SCLKME bit to determine the source for the input clock. A reset selects the CPU clock as the input clock and forces the CLKG frequency to ½ the LSPCLK frequency. The input clock for the sample rate generator is taken from the MCLKR pin, depending on the value of the SCLKME bit of PCR: **SCLKME** / **CLKSM** / **Input Clock For Sample Rate Generator** 0 / 0 / Reserved 1 / 0 / Signal on MCLKR pin
		1	The input clock for the sample rate generator is taken from the LSPCLK or from the MCLKX pin, depending on the value of the SCLKME bit of PCR: **SCLKME** / **CLKSM** / **Input Clock For Sample Rate Generator** 0 / 1 / LSPCLK 1 / 1 / Signal on MCLKX pin
12	FSGM		Sample rate generator transmit frame-synchronization mode bit. The transmitter can get frame synchronization from the FSX pin (FSXM = 0) or from inside the McBSP (FSXM = 1). When FSXM = 1, the FSGM bit determines how the McBSP supplies frame-synchronization pulses.
		0	If FSXM = 1, the McBSP generates a transmit frame-synchronization pulse when the content of DXR[1,2] is copied to XSR[1,2].
		1	If FSXM = 1, the transmitter uses frame-synchronization pulses generated by the sample rate generator. Program the FWID bits to set the width of each pulse. Program the FPER bits to set the period between pulses.
11-0	FPER	0-FFFh	Frame-synchronization period bits for FSG. The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. The period between frame-synchronization pulses on FSG is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles: 0 ≤ FPER ≤ 4095 1 ≤ (FPER + 1) ≤ 4096 CLKG cycles The width of each frame-synchronization pulse on FSG is defined by the FWID bits.

34.15.8 Multichannel Control Registers (MCR[1,2])

Each McBSP has two multichannel control registers. MCR1 (Table 34-90) has control and status bits (with an R prefix) for multichannel selection operation in the receiver. MCR2 (Table 34-91) contains the same type of bits (bit with an X prefix) for the transmitter. These registers enable you to:

- Enable all channels or only selected channels for reception (RMCM)
- Choose which channels are enabled/disabled and masked/unmasked for transmission (XMCM)
- Specify whether two partitions (32 channels at a time) or eight partitions (128 channels at a time) can be used (RMCME for reception, XMCME for transmission)
- Assign blocks of 16 channels to partitions A and B when the 2-partition mode is selected (RPABLK and RPBBLK for reception, XPABLK and XPBBLK for transmission)
- Determine which block of 16 channels is currently involved in a data transfer (RCBLK for reception, XCBLK for transmission)

34.15.8.1 Multichannel Control 1 Register (MCR1)

The multichannel control 1 register (MCR1) is shown in Figure 34-77 and described in Table 34-90.

Figure 34-77. Multichannel Control 1 Register (MCR1)

15	10	9	8
Reserved		RMCME	RPBBLK

7	6	5	4	2	1	0
RPBBLK	RPABLK		RCBLK		Reserved	RMCM
R/W-0	R/W-0		R-0		R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 34-90. Multichannel Control 1 Register (MCR1) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reserved bits (not available for your use). They are read-only bits and return 0s when read.
9	RMCME		Receive multichannel partition mode bit. RMCME is only applicable if channels can be individually enabled or disabled for reception (RMCM = 1). RMCME determines whether only 32 channels or all 128 channels are to be individually selectable.
		0	2-partition mode Only partitions A and B are used. You can control up to 32 channels in the receive multichannel selection mode (RMCM = 1). Assign 16 channels to partition A with the RPABLK bits. Assign 16 channels to partition B with the RPBBLK bits. You control the channels with the appropriate receive channel enable registers: RCERA: Channels in partition A RCERB: Channels in partition B
		1	8-partition mode All partitions (A through H) are used. You can control up to 128 channels in the receive multichannel selection mode. You control the channels with the appropriate receive channel enable registers: RCERA: Channels 0 through 15 RCERB: Channels 16 through 31 RCERC: Channels 32 through 47 RCERD: Channels 48 through 63 RCERE: Channels 64 through 79 RCERF: Channels 80 through 95 RCERG: Channels 96 through 111 RCERH: Channels 112 through 127

Table 34-90. Multichannel Control 1 Register (MCR1) Field Descriptions (continued)

Bit	Field	Value	Description
8-7	RPBBLK	0-3h	Receive partition B block bits RPBBLK is only applicable if channels can be individually enabled or disabled (RMCM = 1) and the 2-partition mode is selected (RMCME = 0). Under these conditions, the McBSP receiver can accept or ignore data in any of the 32 channels that are assigned to partitions A and B of the receiver. The 128 receive channels of the McBSP are divided equally among 8 blocks (0 through 7). When RPBBLK is applicable, use RPBBLK to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B. Use the RPABLK bits to assign one of the even-numbered blocks (0, 2, 4, or 6) to partition A. If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the receiver is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The RCBLK bits are regularly updated to indicate which block is active. When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK).
		0	Block 1: channels 16 through 31
		1h	Block 3: channels 48 through 63
		2h	Block 5: channels 80 through 95
		3h	Block 7: channels 112 through 127
6-5	RPABLK	0-3h	Receive partition A block bits RPABLK is only applicable if channels can be individually enabled or disabled (RMCM = 1) and the 2-partition mode is selected (RMCME = 0). Under these conditions, the McBSP receiver can accept or ignore data in any of the 32 channels that are assigned to partitions A and B of the receiver. See the description for RPBBLK (bits 8-7) for more information about assigning blocks to partitions A and B.
		0	Block 0: channels 0 through 15
		1h	Block 2: channels 32 through 47
		2h	Block 5: channels 64 through 79
		3h	Block 7: channels 96 through 111
4-2	RCBLK	0-7h	Receive current block indicator. RCBLK indicates which block fo 16 channels is involved in the current McBSP reception:
		0	Block 0: channels 0 through 15
		1h	Block 1: channels 16 through 31
		2h	Block 2: channels 32 through 47
		3h	Block 3: channels 48 through 63
		4h	Block 4: channels 64 through 79
		5h	Block 5: channels 80 through 95
		6h	Block 6: channels 96 through 111
		7h	Block 7: channels 112 through 127
1	Reserved	0	Reserved bits (not available for your use). They are read-only bits and return 0s when read.
0	RMCM		Receive multichannel selection mode bit. RMCM determines whether all channels or only selected channels are enabled for reception:
		0	All 128 channels are enabled.
		1	Multichanneled selection mode. Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit.

34.15.8.2 Multichannel Control 2 Register (MCR2)

The multichannel control 2 register (MCR2) is shown in Figure 34-78 and described in Table 34-91.

Figure 34-78. Multichannel Control 2 Register (MCR2)

15	10	9	8
Reserved		XMCME	XPBBLK
R-0		R/W-0	R/W-0

7	6	5	4	2	1	0
XPBBLK	XPABLK		XCBLK		XMCM	
R/W-0	R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 34-91. Multichannel Control 2 Register (MCR2) Field Descriptions

Bit	Field	Value	Description
15-10	Reserved	0	Reserved bits (not available for your use). They are read-only bits and return 0s when read.
9	XMCME		Transmit multichannel partition mode bit. XMCME determines whether only 32 channels or all 128 channels are to be individually selectable. XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero).
		0	2-partition mode. Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bits. If XMCM = 01b or 10b, assign 16 channels to partition A with the XPABLK bits. Assign 16 channels to partition B with the XPBBLK bits. If XMCM = 11b(for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bits. Assign 16 channels to receive partition B with the RPBBLK bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels in partition A XCERB: Channels in partition B
		1	8-partition mode. All partitions (A through H) are used. You can control up to 128 channels in the transmit multichannel selection mode selected with the XMCM bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels 0 through 15 XCERB: Channels 16 through 31 XCERC: Channels 32 through 47 XCERD: Channels 48 through 63 XCERE: Channels 64 through 79 XCERF: Channels 80 through 95 XCERG: Channels 96 through 111 XCERH: Channels 112 through 127

Table 34-91. Multichannel Control 2 Register (MCR2) Field Descriptions (continued)

Bit	Field	Value	Description
8-7	XPBBLK	0-3h	Transmit partition B block bits XPBBLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter. The 128 transmit channels of the McBSP are divided equally among 8 blocks (0 through 7). When XPBBLK is applicable, use XPBBLK to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B, as shown in the following table. Use the XPABLK bit to assign one of the even-numbered blocks (0, 2, 4, or 6) to partition A. If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the transmitter is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The XCBLK bits are regularly updated to indicate which block is active. When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK).
		0	Block 1: channels 16 through 31
		1h	Block 3: channels 48 through 63
		2h	Block 5: channels 80 through 95
		3h	Block 7: channels 112 through 127
6-5	XPABLK		Transmit partition A block bits. XPABLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter. See the description for XPBBLK (bits 8-7) for more information about assigning blocks to partitions A and B.
		0	Block 0: channels 0 through 15
		1h	Block 2: channels 32 through 47
		2h	Block 4: channels 64 through 79
		3h	Block 6: channels 96 through 111
4-2	XCBLK		Transmit current block indicator. XCBLK indicates which block of 16 channels is involved in the current McBSP transmission:
		0	Block 0: channels 0 through 15
		1h	Block 1: channels 16 through 31
		2h	Block 2: channels 32 through 47
		3h	Block 3: channels 48 through 63
		4h	Block 4: channels 64 through 79
		5h	Block 5: channels 80 through 95
		6h	Block 6: channels 96 through 111
		7h	Block 7: channels 112 through 127
1-0	XMCM	0-3h	Transmit multichannel selection mode bits. XMCM determines whether all channels or only selected channels are enabled and unmasked for transmission. For more details on how the channels are affected, see Section 34.6.7 .
		0	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
		1h	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked. The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs.
		2h	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs.
		3h	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit determines whether 32 channels or 128 channels are selectable in RCERs and XCERs.

34.15.9 Pin Control Register (PCR)

Each McBSP has one pin control register (PCR). Table 34-92 describes the bits of PCR. This register enables you to:

- Choose a frame-synchronization mode for the transmitter (FSXM) and for the receiver (FSRM)
- Choose a clock mode for transmitter (CLKXM) and for the receiver (CLKRM)
- Select the input clock source for the sample rate generator (SCLKME, in conjunction with the CLKSM bit of SRGR2)
- Choose whether frame-synchronization signals are active low or active high (FSXP for transmission, FSRP for reception)
- Specify whether data is sampled on the falling edge or the rising edge of the clock signals (CLKXP for transmission, CLKRP for reception)

The pin control register (PCR) is shown in Figure 34-79 and described in Table 34-92.

Figure 34-79. Pin Control Register (PCR)

15	12	11	10	9	8
Reserved		FSXM	FSRM	CLKXM	CLKRM
R-0		R/W-0	R/W-0	R/W-0	R/W-0

7	6	4	3	2	1	0
SCLKME	Reserved		FSXP	FSRP	CLKXP	CLKRP
R/W-0	R-0		R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 34-92. Pin Control Register (PCR) Field Descriptions

Bit	Field	Value	Description
15:12	Reserved	0	Reserved bit (not available for your use). It is a read-only bit and returns a 0 when read.
11	FSXM		Transmit frame-synchronization mode bit. FSXM determines whether transmit frame-synchronization pulses are supplied externally or internally. The polarity of the signal on the FSX pin is determined by the FSXP bit.
		0	Transmit frame synchronization is supplied by an external source via the FSX pin.
		1	Transmit frame synchronization is generated internally by the Sample Rate generator, as determined by the FSGM bit of SRGR2.
10	FSRM		Receive frame-synchronization mode bit. FSRM determines whether receive frame-synchronization pulses are supplied externally or internally. The polarity of the signal on the FSR pin is determined by the FSRP bit.
		0	Receive frame synchronization is supplied by an external source via the FSR pin.
		1	Receive frame synchronization is supplied by the sample rate generator. FSR is an output pin reflecting internal FSR, except when GSYNC = 1 in SRGR2.

Table 34-92. Pin Control Register (PCR) Field Descriptions (continued)

Bit	Field	Value	Description
9	CLKXM		Transmit clock mode bit. CLKXM determines whether the source for the transmit clock is external or internal, and whether the MCLKX pin is an input or an output. The polarity of the signal on the MCLKX pin is determined by the CLKXP bit. In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master, make sure that CLKX is an output. If the McBSP is a slave, make sure that CLKX is an input. Not in clock stop mode (CLKSTP = 00b or 01b):
		0	The transmitter gets its clock signal from an external source via the MCLKX pin.
		1	Internal CLKX is driven by the sample rate generator of the McBSP. The MCLKX pin is an output pin that reflects internal CLKX.
			In clock stop mode (CLKSTP = 10b or 11b):
		0	The McBSP is a slave in the SPI protocol. The internal transmit clock (CLKX) is driven by the SPI master via the MCLKX pin. The internal receive clock (MCLKR) is driven internally by CLKX, so that both the transmitter and the receiver are controlled by the external master clock.
		1	The McBSP is a master in the SPI protocol. The sample rate generator drives the internal transmit clock (CLKX). Internal CLKX is reflected on the MCLKX pin to drive the shift clock of the SPI-compliant slaves in the system. Internal CLKX also drives the internal receive clock (MCLKR), so that both the transmitter and the receiver are controlled by the internal master clock.
8	CLKRM		Receive clock mode bit. The role of CLKRM and the resulting effect on the MCLKR pin depend on whether the McBSP is in the digital loopback mode (DLB = 1). The polarity of the signal on the MCLKR pin is determined by the CLKRP bit. Not in digital loopback mode (DLB = 0):
		0	The MCLKR pin is an input pin that supplies the internal receive clock (MCLKR).
		1	Internal MCLKR is driven by the sample rate generator of the McBSP. The MCLKR pin is an output pin that reflects internal MCLKR.
			In digital loopback mode (DLB = 1):
		0	The MCLKR pin is in the high impedance state. The internal receive clock (MCLKR) is driven by the internal transmit clock (CLKX). CLKX is derived according to the CLKXM bit.
		1	Internal MCLKR is driven by internal CLKX. The MCLKR pin is an output pin that reflects internal MCLKR. CLKX is derived according to the CLKXM bit.
7	SCLKME		Sample rate generator input clock mode bit. The sample rate generator can produce a clock signal, CLKG. The frequency of CLKG is: CLKG freq. = (Input clock frequency) / (CLKGDV + 1) SCLKME is used in conjunction with the CLKSM bit to select the input clock. **SCLKME** / **CLKSM** / **Input Clock For Sample Rate Generator** 0 / 0 / Reserved 0 / 1 / LSPCLK The input clock for the sample rate generator is taken from the MCLKR pin or from the MCLKX pin, depending on the value of the CLKSM bit of SRGR2: **SCLKME** / **CLKSM** / **Input Clock For Sample Rate Generator** 1 / 0 / Signal on MCLKR pin 1 / 1 / Signal on MCLKX pin
6-4	Reserved		Reserved
3	FSXP		Transmit frame-synchronization polarity bit. FSXP determines the polarity of FSX as seen on the FSX pin.
		0	Transmit frame-synchronization pulses are active high.
		1	Transmit frame-synchronization pulses are active low.
2	FSRP		Receive frame-synchronization polarity bit. FSRP determines the polarity of FSR as seen on the FSR pin.
		0	Receive frame-synchronization pulses are active high.
		1	Receive frame-synchronization pulses are active low.

Table 34-92. Pin Control Register (PCR) Field Descriptions (continued)

Bit	Field	Value	Description
1	CLKXP		Transmit clock polarity bit. CLKXP determines the polarity of CLKX as seen on the MCLKX pin.
		0	Transmit data is sampled on the rising edge of CLKX.
		1	Transmit data is sampled on the falling edge of CLKX.
0	CLKRP		Receive clock polarity bit. CLKRP determines the polarity of CLKR as seen on the MCLKR pin.
		0	Receive data is sampled on the falling edge of MCLKR.
		1	Receive data is sampled on the rising edge of MCLKR.

Table 34-93. Pin Configuration

Pin	Selected as Output When …	Selected as Input When …
CLKX	CLKXM = 1	CLKXM = 0
FSX	FSXM = 1	FSXM = 0
CLKR	CLKRM = 1	CLKRM = 0
FSR	FSRM = 1	FSRM = 0

34.15.10 Receive Channel Enable Registers (RCERA, RCERB, RCERC, RCERD, RCERE, RCERF, RCERG, RCERH)

Each McBSP has eight receive channel enable registers of the format shown in Figure 34-80. There is one enable register for each of the receive partitions: A, B, C, D, E, F, G, and H. Table 34-94 provides a summary description that applies to any bit x of a receive channel enable register.

These memory-mapped registers are only used when the receiver is configured to allow individual enabling and disabling of the channels (RMCM = 1). For more details about the way these registers are used, see Section 34.15.10.1.

The receive channel enable registers (RCERA...RCERH) are shown in Figure 34-80 and described in Table 34-94.

Figure 34-80. Receive Channel Enable Registers (RCERA...RCERH)

15	14	13	12	11	10	9	8

Table 34-94. Receive Channel Enable Registers (RCERA...RCERH) Field Descriptions

Bit	Field	Value	Description
15-0	RCEx		Receive channel enable bit.
			For receive multichannel selection mode (RMCM = 1):
		0	Disable the channel that is mapped to RCEx.
		1	Enable the channel that is mapped to RCEx.

34.15.10.1 RCERs Used in the Receive Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the RCERs depends on whether 32 or 128 channels are individually selectable, as defined by the RMCME bit. For each of these two cases, Table 34-95 shows which block of channels is assigned to each of the RCERs used. For each RCER, the table shows which channel is assigned to each of the bits.

Table 34-95. Use of the Receive Channel Enable Registers

Number of Selectable Channels	Block Assignments		Channel Assignments	
	RCERx	Block Assigned	Bit in RCERx	Channel Assigned
32 (RMCME = 0)	RCERA	Channels n to (n + 15)	RCE0	Channel n

34.15.11 Transmit Channel Enable Registers (XCERA, XCERB, XCERC, XCERD, XCERE, XCERF, XCERG, XCERH)

Each McBSP has eight transmit channel enable registers of the form shown in Figure 34-81. There is one for each of the transmit partitions: A, B, C, D, E, F, G, and H. Table 34-96 provides a summary description that applies to each bit XCEx of a transmit channel enable register.

The XCERs are only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (XMCM is nonzero).

The transmit channel enable registers (XCERA...XCERH) are shown in Figure 34-81 and described in Table 34-96.

Figure 34-81. Transmit Channel Enable Registers (XCERA...XCERH)

15	14	13	12	11	10	9	8

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 34-96. Transmit Channel Enable Registers (XCERA...XCERH) Field Descriptions

Bit	Field	Value	Description
15-0	XCEx		Transmit channel enable bit. The role of this bit depends on which transmit multichannel selection mode is selected with the XMCM bits.
			For multichannel selection when XMCM = 01b (all channels disabled unless selected):
		0	Disable and mask the channel that is mapped to XCEx.
		1	Enable and unmask the channel that is mapped to XCEx.
			For multichannel selection when XMCM = 10b (all channels enabled but masked unless selected):
		0	Mask the channel that is mapped to XCEx.
		1	Unmask the channel that is mapped to XCEx.
			For multichannel selection when XMCM = 11b (all channels masked unless selected):
		0	Mask the channel that is mapped to XCEx. Even if the channel is enabled by the corresponding receive channel enable bit, this channel's data cannot appear on the DX pin.
		1	Unmask the channel that is mapped to XCEx. If the channel is also enabled by the corresponding receive channel enable bit, full transmission can occur.

34.15.12 XCERs Used in a Transmit Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the XCERs depends on whether 32 or 128 channels are individually selectable, as defined by the XMCME bit. These two cases are shown in Table 34-97. The table shows which block of channels is assigned to each XCER that is used. For each XCER, the table shows which channel is assigned to each of the bits.

NOTE: When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive channel enable registers (RCERs) to enable channels and uses the XCERs to unmask channels for transmission.

Table 34-97. Use of the Transmit Channel Enable Registers

Number of Selectable Channels	Block Assignments		Channel Assignments	
	XCERx	Block Assigned	Bit in XCERx	Channel Assigned
32 (XMCME = 0)	XCERA	Channels n to (n + 15)	XCE0	Channel n

Power Management Bus Module (PMBus)

This chapter describes the features and operation of the Power Management Bus (PMBus) module.

Topic **Page**

35.1 Introduction

The PMBus module provides an interface between the microcontroller and devices compliant with the SMI Forum PMBus Specification Part I version 1.0 and Part II version 1.1. PMBus is based on SMBus, which uses a similar physical layer to I2C. This guide assumes the reader is familiar with the PMBus, SMBus, and I2C bus specifications.

35.1.1 Features

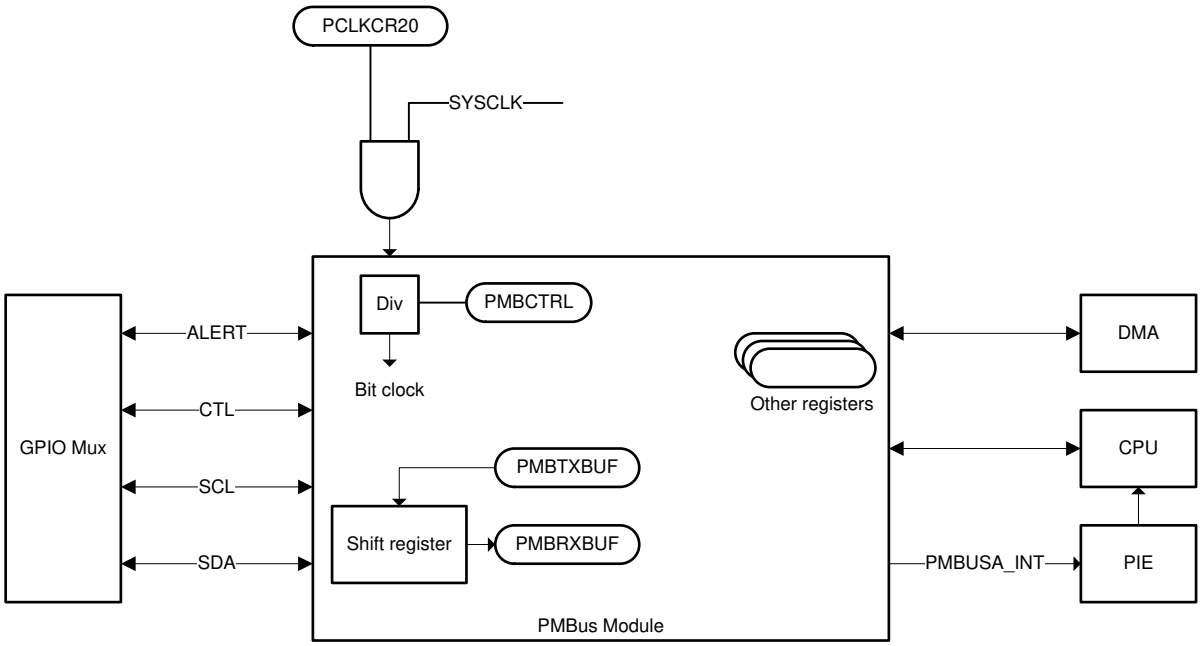
The PMBus module has the following features:

- Compliance with the SMI Forum PMBus Specification (Part I v1.0 and Part II v1.1)
- Support for master and slave modes
- Support for I2C modes
- Support for three speeds:
  - Standard Mode: Up to 100 kHz
  - Fast Mode: Up to 400 kHz
- Packet error checking
- CONTROL and ALERT signals
- Clock high and low time-outs
- Four-byte transmit and receive buffers
- One maskable interrupt, which can be generated by several conditions:
  - Receive data ready
  - Transmit buffer empty
  - Slave address received
  - End of message
  - ALERT input asserted
  - Clock low time-out
  - Clock high time-out
  - Bus free

35.1.2 Functional Description

The following figure shows the block diagram for PMBus.

Figure 35-1. PMBus Module Conceptual Block Diagram



The PMBus module handles the lower levels of the PMBus protocol. In addition to controlling signal levels and timing, parsing addresses, and buffering data, it also directly supports complex transactions such as Read Word and Process Call.

There are four PMBus signals: SCL, SDA, CONTROL, and ALERT.

- SCL is the bus clock. It is normally controlled by the master, but may be held low by a slave to delay a transaction and allow more time for processing.
- SDA is the bidirectional data line.
- CONTROL is a slave input that can trigger an interrupt. It can be used to tell a slave device to shut down.
- ALERT is a slave output/master input that allows a slave to request attention from the master.

The SDA and SCL timings produced by the module are derived from SYSCLK. To comply with the PMBus timing specs, the bit clock divider must be set via the PMBTIMCLK register to provide a bit clock of 10 MHz or less.

35.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification is set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups are configured in the GPyPUD register.

NOTE: The GPIO configuration register GPyODR must be set to normal mode when the PMBus is used. The open-drain operation for PMBus is managed by the PMBus module

See the *GPIO* chapter for more details on GPIO mux and settings.

35.3 Slave Mode Operation

This section describes the configuration and operation of the PMBus module in slave mode.

35.3.1 Configuration

To configure the module, write a suitable clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10 MHz. To activate slave mode, set the SLAVE_EN bit in the PMBCTRL register. Next, set up the PMBSC register. The following options are configurable:

- Slave address and mask (SLAVE_ADDR and SLAVE_MASK): Sets the slave address and mask for message acceptance.
- Manual slave address acknowledgement (MAN_SLAVE_ACK): When enabled, allows software to decide whether to acknowledge (ACK) an address. When disabled, the decision to ACK is made automatically based on the slave address and mask.
- PEC enable (PEC_ENA): Set this bit if Packet Error Checking (PEC) is used on the bus.
- Manual command byte acknowledgement (MAN_CMD): Similar to manual slave acknowledgement, setting this bit allows software to decide whether to acknowledge (ACK) a command byte.
- Number of bytes to acknowledge automatically (RX_BYTE_ACK_CNT): This is normally set to the max value, which allows the entire receive buffer to be used. However, smaller values may be used if the application requires that erroneous messages be detected and not acknowledged (NACKed) as soon as possible.

Manual acknowledgement is done by writing a one to the PMBACK register. Even with automatic acknowledgement, some writes to PMBACK are required. If the message (not including the address) is longer than 4 bytes, each packet of 4 bytes much be acknowledged. The PMBus module will stretch the clock (hold it low) until an ACK is issued. The module will then pull the data line low and release the clock, providing the ACK signal to the master.

If the complete message or the last part of the message is less than 4 bytes (or the RX_BYTE_ACK_CNT limit), do not write to PMBACK.

Writing a zero to the PMBACK bit will send a NACK. This may only be done when the module is waiting for an acknowledgement. If a zero is written at any other time, the NACK will be issued during the next message.

35.3.2 Message Handling

This section describes some of the message types for PMBus and how to determine which message type is being received in slave mode. It is oriented toward the most efficient mode of operation – with automatic address and command acknowledgment. It is also oriented toward having Packet Error Checking (PEC) enabled.

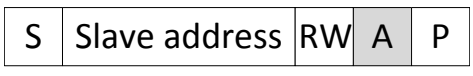
If automatic address acknowledgement is disabled, all messages will start by setting the SLAVE_ADDR_READY register bit high. Read commands will have two instructions one for the read, and one for the write. If automatic command acknowledgement is enabled, the DATA READY bit will be set high, as well. If the message has no PEC, the number of bytes available will be n-1. For example, with PEC, a QUICK COMMAND will have one byte. With no PEC, a QUICK COMMAND will have zero bytes.

Note that the byte count does not increment as bytes arrive. No bits are set in the PMBST register until a stop message is received, the receive buffer is full, or a fault occurs. Then, all appropriate bit values are placed in the register together. All that is necessary to receive a quick command is to ACK the message by writing a one to the PMBACK register.

35.3.2.1 Quick Command

Quick Commands received by the PMBus module in slave mode require a simple acknowledgment of the received device address. In automatic address acknowledge mode, the module processes the quick command without firmware interaction. Upon receipt of the end of message, the firmware has the option to read the received address in the PMBHSA register. In manual address acknowledge mode, the address is acknowledged by writing to the PMBACK register.

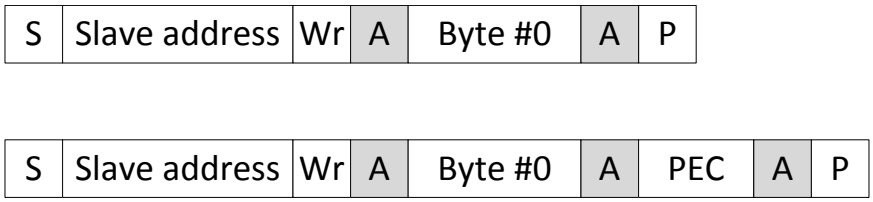
Figure 35-2. Quick Command Message



35.3.2.2 Send Byte

A Send Byte message consists of the device address, a single data byte and an optional PEC byte. To process the PEC byte correctly, PEC processing must be enabled in the PMBSC register. In automatic address acknowledge mode, the data and optional PEC byte are acknowledged without firmware interaction. The module generates an End of Message interrupt, reads the status register and finds the data ready indication bit set. In manual mode, the address is acknowledged by the firmware, while the remaining data and PEC bytes are acknowledged by the module

Figure 35-3. Send Byte Message with and without PEC



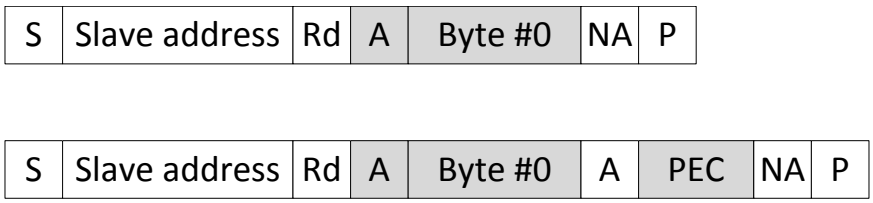
The PMBus module stores Data Byte #0 into the PMBRXBUF register. The data byte will be stored into bits 7-0. In non-PEC mode, the RX Byte Count in the PMBSTS register will indicate one byte received. If PEC processing is enabled, the PEC byte is also stored into the PMBRXBUF register, with the PEC byte residing in bits 15-8. The RX Byte Count in the PMBSTS register will indicate two bytes received. The PEC Valid bit in the PMBSTS register indicates the validity of the received PEC byte.

When a Send Byte message is received, the Data Ready bit is set along with the EOM and, assuming that the PEC is valid, the PEC valid bit. The read byte count (RD_BYTE_COUNT) register will contain a 2. All that is necessary to receive a send byte command is to ACK the message by writing a 1 to the PMBACK register. Before doing the ACK, read the byte from the lowest byte of the PMBRXBUF register.

35.3.2.3 Receive Byte

A Receive Byte message consists of the device address, a single data byte and an optional PEC byte. In automatic address acknowledge mode, the firmware receives a data request interrupt following reception of the slave address. The data byte to be sent to the master is stored into bits 7-0 of the PMBTXBUF register and Transmit Byte Count bits within the PMBSC register are set to a value of one. If PEC processing is enabled, the Transmit PEC bit (bit 19) within the PMBSC register is set to ‘1’, along with the Enable PEC bit (bit 15). The module will automatically append the calculated PEC byte at the completion of the message.

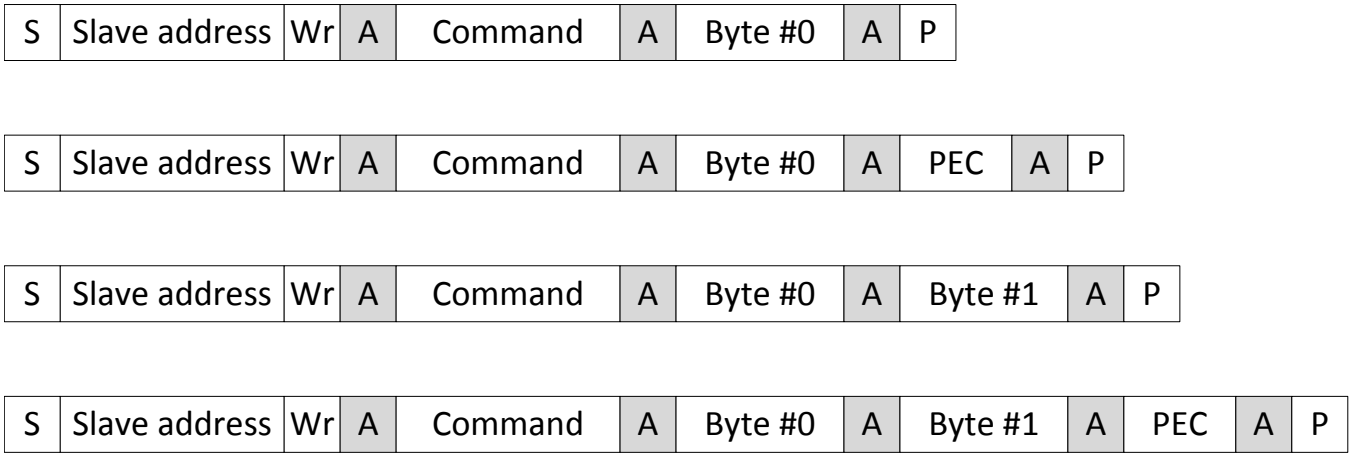
Figure 35-4. Receive Byte Message with and without PEC



35.3.2.4 Write Byte/Word

The Write Byte and Write Word messages consist of a slave address, a command word, transmitted data bytes and an optional PEC byte. In automatic address acknowledge mode, the data bytes and optional PEC byte are acknowledged without firmware interaction. The acknowledgment of the command word is configured through the PMBSC register. The firmware receives an End of Message interrupt in all cases except for Write Word with PEC message, reads the status register and finds the data ready indication bit set.

Figure 35-5. Write Byte and Write Word Messages with and without PEC



In the case of a Write Word with PEC byte message, the data ready interrupt is enabled after receiving 4 bytes (command byte, the 2 data bytes and the PEC byte). The firmware reads the data from the PMBRXBUF register and must write the PMBACK register to acknowledge back to the master. The PMBus module holds SCL low until the firmware responds to the received data.

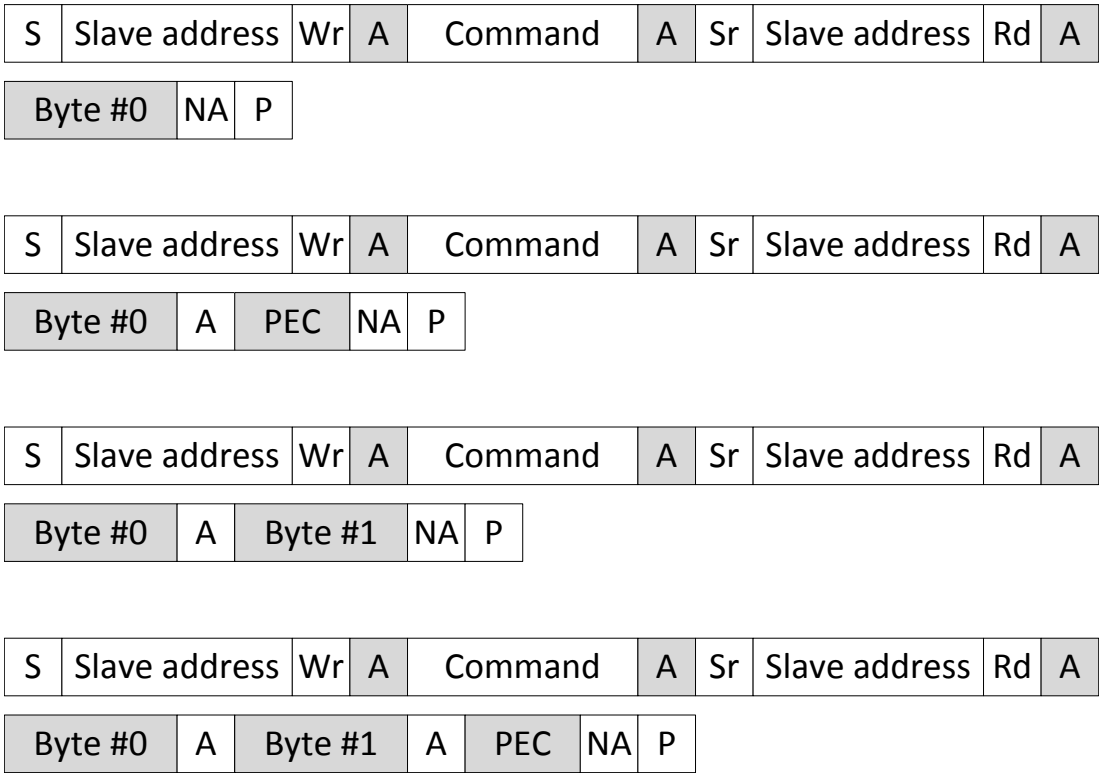
In all other cases, the EOM interrupt is received and data can be read from the PMBRXBUF register. The firmware is not required to send an acknowledgement back to the master.

The Write Byte message will look exactly the same as the Send Byte, except the RD_BYTE_COUNT register will contain a 3. The Write Word message will have a RD_BYTE_COUNT of 4.

35.3.2.5 Read Byte/Word

The Read Byte and Read Word messages consist of a slave address, a command word, received data bytes from a slave, and an optional PEC byte. Address and command acknowledgment is configured through the PMBSC register. In automatic mode, the PMBus module provides a data ready and data request interrupt following receipt of a repeated start and slave address. The received command byte is found in bits 7-0 of the PMBRXBUF register. The firmware responds to the data request by programming the data bytes into the PMBTXBUF register and the TX Byte Count bits in the PMBSC register. If PEC processing is enabled, the Transmit PEC bit should also be asserted. An EOM interrupt indicates completion of the message to the Master.

Figure 35-6. Read Byte and Read Word Messages with and without PEC



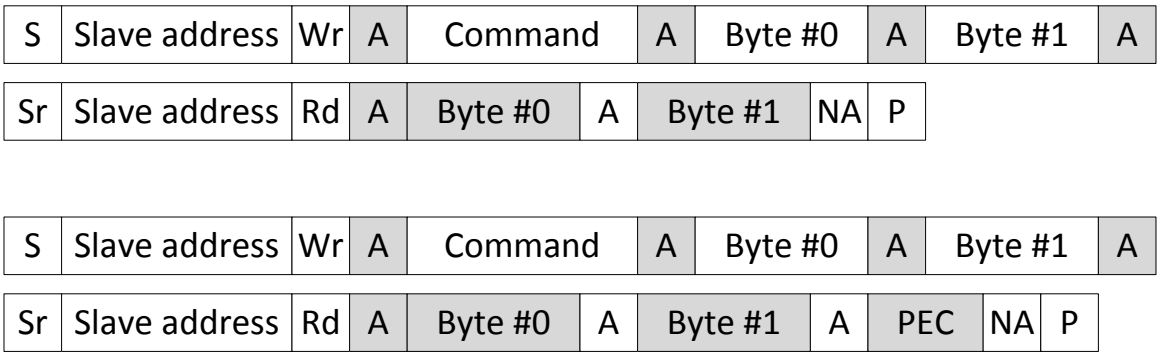
When the repeated start (Sr) signal is received, the Data Ready bit will be asserted with a RD_BYTE_COUNT of 1. At this point, the operation cannot be distinguished from a group command Send Byte message. When the same device address is sent out with a read, the Data Request bit will be asserted. If data has already been written to the PMTXBUF register before the Device Addr is received, the Data Request bit will not be asserted. So if group commands are also expected, it is necessary to read the Data Ready with a RD_BYTE_COUNT of 1, and then wait and see whether the next event is an EOM or a Data Request. If it is an EOM, the command should be processed as a group send byte. If it is a Data Request, the command should be processed as a read. Depending on the command, it could be a read byte, word, or block. If the PMBus module is polled, both the Data Ready and the Data Request bits could possibly be set between polling intervals. This should be considered in the design of the firmware.

Once the read command is recognized, you must respond by writing data to the PMBTXBUF register. It is also necessary to make sure that the values in the PMBSC register are correct. The transmit byte count and PEC bit must be set appropriately. For a read byte, the transmit byte count can be loaded with a 1. If the transmission of a PEC byte is desired, the TX_PEC bit must be set. After this, the data can be written to PMBTXBUF, which starts the transmission. All bytes should be written to PMBTXBUF at the same time. After the master receives the message, it will NACK the last byte to indicate that the correct number of bytes have been received. This will cause the EOM bit to be set in the PMBSTS register, indicating to the firmware that the Read Byte message is complete.

35.3.2.6 Process Call

The Process Call protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. Address and command acknowledgement is configured through the PMBSC register. In automatic mode, following receipt of the repeated start and slave address, the PMBus module provides a data ready and a data request interrupt. The repeated start bit is set in the PMBSTS register to indicate the receipt of the first part of the Process Call message. The received command byte is found in bits 7-0 of the PMBRXBUF register, while the two data bytes received from the master can be found in bits 23-8. Upon receipt of the repeated start and a data request from the module, the firmware programs the PMBTXBUF with the 2 data bytes to be sent to the master. If PEC processing is enabled, the Transmit PEC bit within the PMBSC register is asserted. The EOM interrupt will indicate the read word portion of the Process Call message has been completed by the module

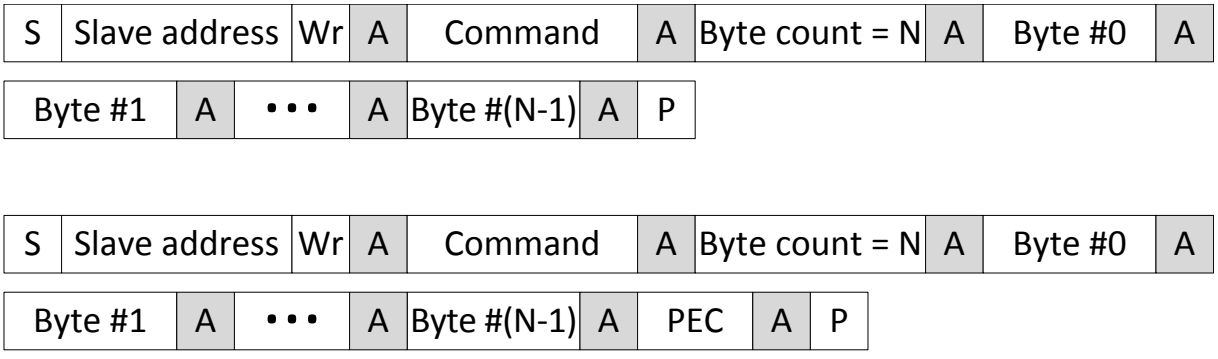
Figure 35-7. Process Call Message with and without PEC



35.3.2.7 Block Write

The Block Write protocol is similar to Write Word in its structure, except that there are more than 2 data bytes in the message. Following the receipt of the command byte, the block length and 2 data bytes, the PMBus module provides a data ready interrupt. The module waits for the firmware to read the received data and program the acknowledge register. While waiting for an ACK from the firmware, the module will drive the clock line low, stalling the bus. The data ready interrupts will continue for the duration of the message at a frequency of every 4 data bytes. The number of bytes received can be found within the PMBSTS register. At the end of the message, less than 4 bytes may be stored in the PMBRXBUF register. The PEC Valid bit can be checked to determine if the received PEC value is accurate.

Figure 35-8. Block Write Message with and without PEC

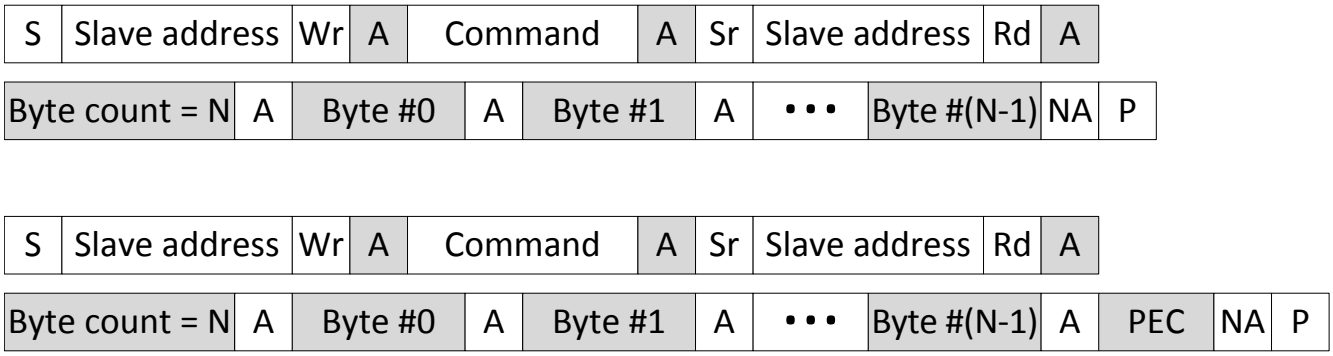


35.3.2.8 Block Read

The Block Read protocol is similar to a Read Word in its structure, except that there are more than 2 data bytes in the message. Following the receipt of the repeated slave address, a data ready and data request interrupt is generated by the PMBus module. The command byte received from the master can be found in bits 7-0 of the PMBRXBUF register. The SCL line is held low until the firmware programs data bytes into the PMBTXBUF register. The firmware is required to load the block length into bits 7-0 of the PMBTXBUF register during the initial programming of the register. After 4 bytes have been transmitted, the module will issue a data request interrupt and hold SCL low again until the firmware has programmed additional data into the PMBTXBUF register.

Block read starts the same as Read Word or Read Byte, but TX_COUNT is loaded with a 4 the first time, and TX_PEC is not set. Instead of waiting for an EOM after the first transmission, the firmware instead waits for a Data Request, indicating that the master is ready for more data. Until the last 4 or less bytes, the firmware simply writes a 4 to TX_COUNT and then writes the 4 bytes to PMBTXBUF. TX_PEC is left cleared. Then when the last 4 or fewer bytes are to be transmitted, the firmware writes out the appropriate byte count, sets the TX_PEC bit, and writes the data to PMBTXBUF. The PMBus module will write out the data, followed by the PEC, and then the EOM bit will be set when the master NACKs the PEC.

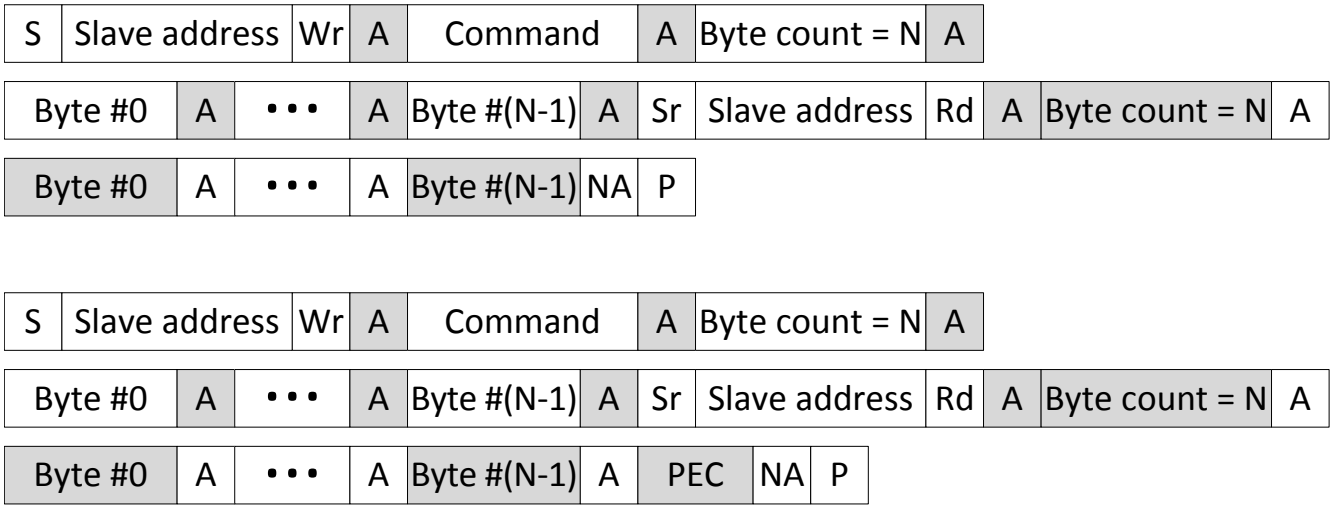
Figure 35-9. Block Read Message with and without PEC



35.3.2.9 Block Write-Block Read Process Call

The Block Read-Block Write Process Call protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The processing of the Block Read-Block Write Process Call message is similar to the mode of operation for the Process Call message. After acknowledgement of the address and command bytes, the PMBus module generates a data ready interrupt upon detection of 4 data bytes or a repeated start condition. After receiving the repeated start, the firmware will be required to load transmit data to send to the master. Bits 7-0 of the initial programming of the PMBTXBUF register must represent the byte count of the block data sent to the master.

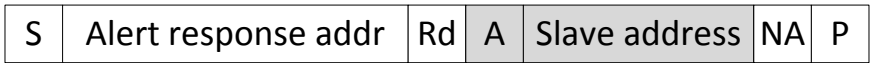
Figure 35-10. Block Write-Block Read Process Call Message with and without PEC



35.3.2.10 Alert Response

The Alert Response Message is utilized when the master detects an alert condition from a slave on the PMBus. In automatic address acknowledge mode, upon detection of the Alert Response Address, the PMBus module provides an acknowledgement to the master and sends the programmed slave address within the PMBSC register. The module only responds to the message if the Alert En bit within PMBCTRL register has been previously set. After receiving the Alert Response message, the module will clear the alert condition and enable bit within the PMBCTRL register.

Figure 35-11. Alert Response Message



In manual address acknowledge mode, the firmware must read the received address from the PMBRXBUF register and transmit the desired slave address back to the master. The PMBCTRL register must be reprogrammed to disable the Alert En bit used to initiate the Alert Response message from the master.

35.3.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. Both command bytes are stored in the PMBRXBUF register along with the data bytes. In recognizing the extended command messages, the Repeated Start bit and the Rd Byte Count Bits within the PMBSTS register are utilized. For Extended Command Write Byte/Write Word messages, the two command bytes are stored in bits 15-0 of the PMBRXBUF register. The initial command byte should hold the command extension code, representing utilization of the extended command protocol. The Repeated Start bit is also set, received after the retransmission of the device address. The Rd Byte Count equals 3 for an Ext Cmd Write Byte message and 4 for an Ext Cmd Write Word message.

Figure 35-12. Extended Command Write Byte and Write Word Messages with and without PEC

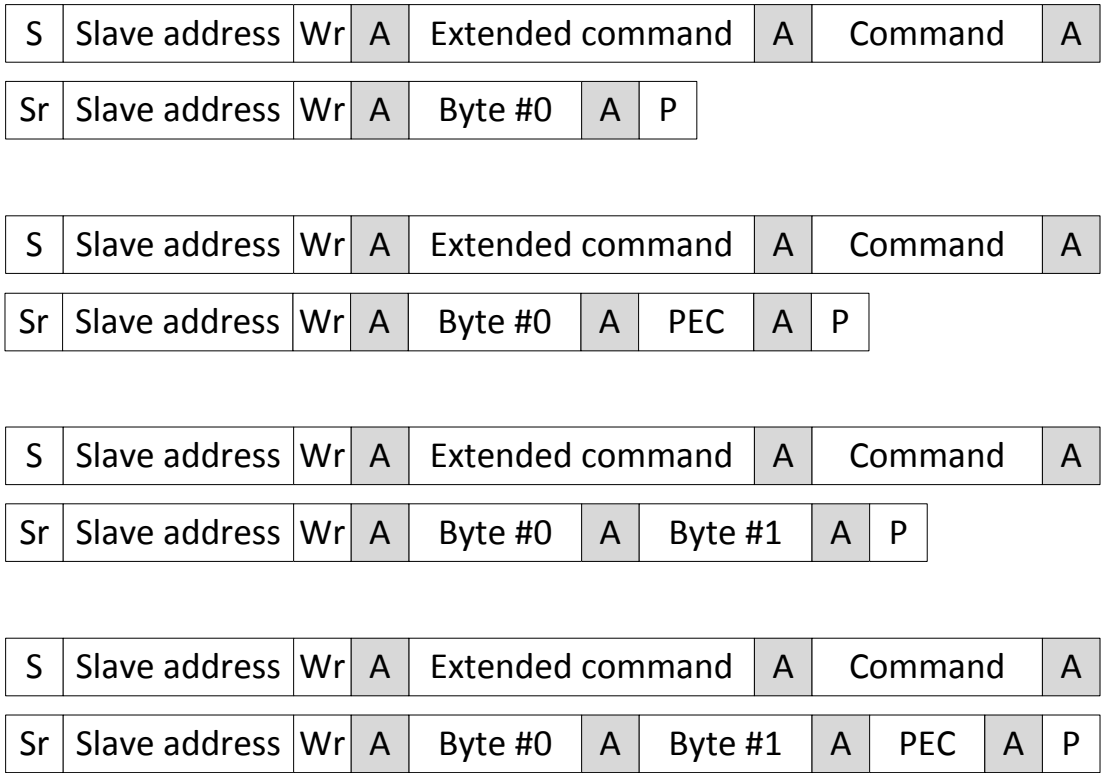


Figure 35-13. Extended Command Write Byte and Write Word Messages with and without PEC

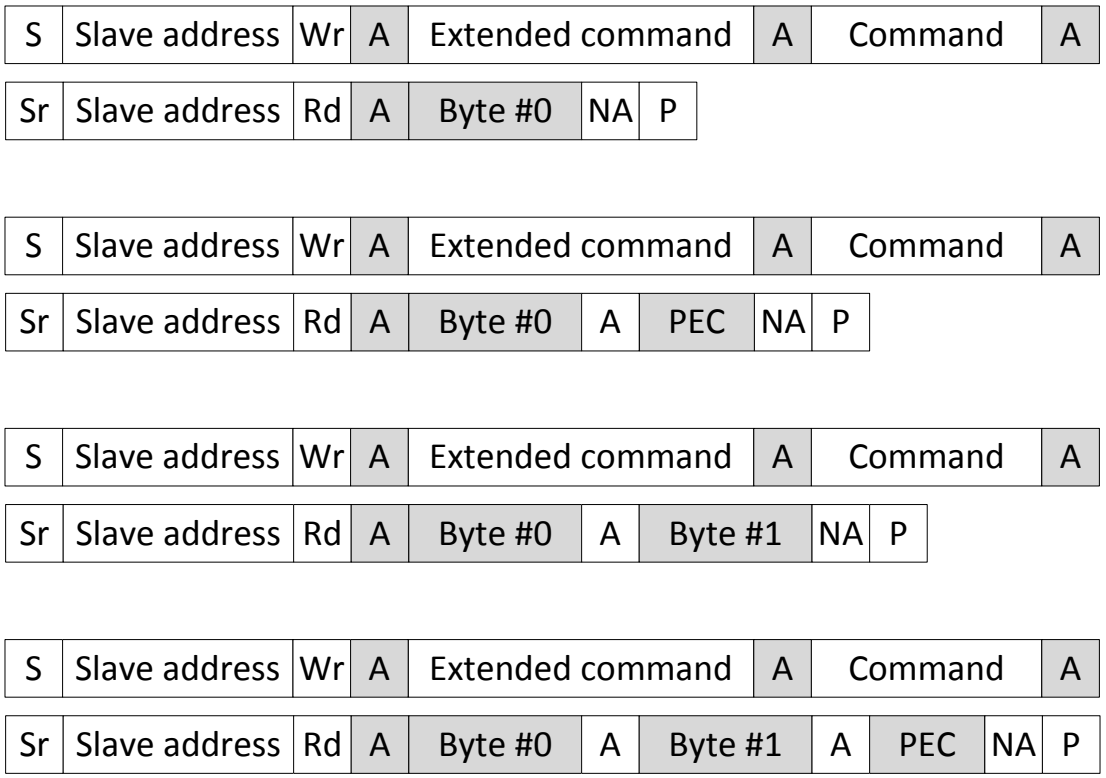
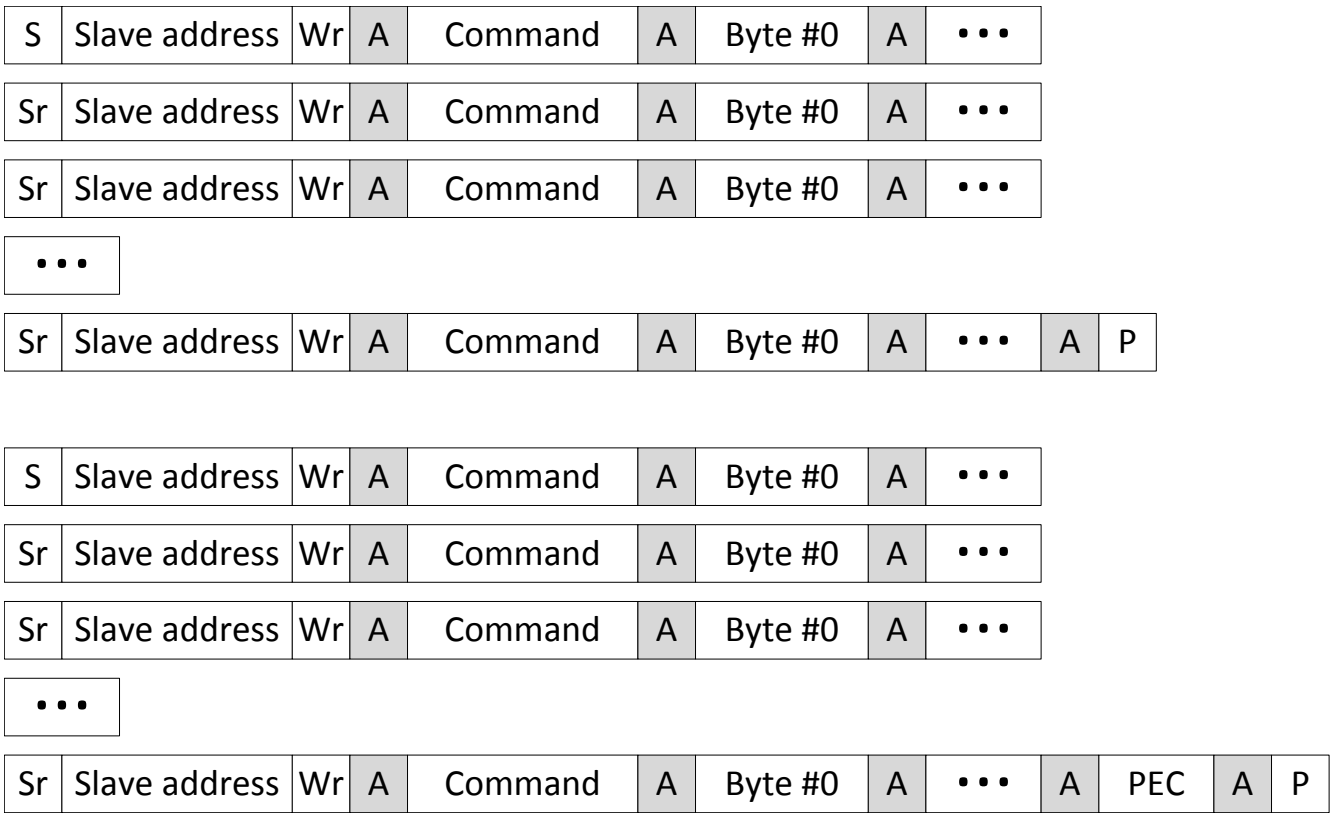


For the Extended Command Read Byte/Read Word messages, the module will generate a data ready and data request interrupt following reception of the repeated device address. The two command bytes will be found in bits 15-0 of the PMBRXBUF register, with the initial command byte matching the command extension code. The firmware will be required to load transmit data to complete the message back to the master.

35.3.2.12 Group Command

The PMBus module supports the Group Command Protocol. The Group Command Protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. Following address and command acknowledgment, the module provides a data ready interrupt upon detection of 4 data bytes or the transmission of a repeated start on the bus. The firmware should wait for the EOM interrupt before processing the received command, as required by the use of the Group Command message.

Figure 35-14. Group Command Message with and without PEC



For Group Commands, the data ready bit will be set as soon as the repeated start is received. The data can then be read into memory. But the data should not be acted upon until the EOM bit is set, which will occur when all of the messages have been received. Other than this delayed EOM, there is no difference for the slave firmware in receiving a Group Command than any other write message.

35.4 Master Mode Operation

This section describes the configuration and operation of the PMBus module in master mode.

35.4.1 Configuration

First, write a suitable clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10 MHz. To activate master mode, set the MASTER_EN bit and clear the SLAVE_EN bit in the PMBCTRL register. For each transaction, set up the PMBMC register. The following options are configurable:

- Slave address (SLAVE_ADDR): Sets the slave address for the next transaction.
- PEC enable (PEC_ENA): If Packet Error Checking (PEC) is used on the bus, set this bit.
- Extended command code enable (EXT_CMD): When set, uses two bytes for commands.
- Command code enable (CMD_ENA): When set, sends a command byte at the start of the transaction.
- Byte count (BYTE_COUNT): Determines the number of data bytes to transfer. This does not include the block length byte, which is generated automatically when needed.
- Special command enables (GRP_CMD and PRC_CALL): Enables special behavior for group commands and process calls.

Writing to the PMBMC register will start a transfer.

Manual acknowledgement of received data is not needed.

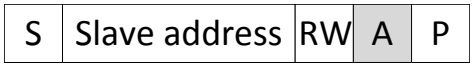
35.4.2 Message Handling

This section describes the behavior and required configuration for each command type.

35.4.2.1 Quick Command

Quick commands are initiated in master mode by simply programming the desired slave device address into the PMBMC. The byte count within the PMBMC register is configured to 0 bytes by writing all zeros to bits 15-8. Upon transmission of the device address, the PMBus module will monitor the slave acknowledgement of the address. If the address is not acknowledged, the NACK bit within the status register is enabled and the PMBus module automatically sends a stop condition on the bus to terminate the message. If the address is acknowledged, a data request is issued to the processor. The firmware writes a zero to the PMBACK to terminate the message, forcing the PMBus modules to write a stop condition onto the bus.

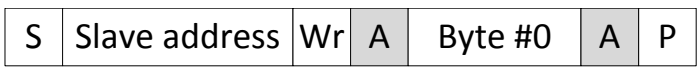
Figure 35-15. Quick Command Message



35.4.2.2 Send Byte

A Send Byte message consists of the device address, a single data byte and an optional PEC byte. To initiate a Send Byte message, the data byte to be transmitted to the slave is loaded into bits 7-0 of the PMBTXBUF register. The PMBMC register is configured with the device address. To transmit a PEC byte with the message, the PEC_EN bit within the PMBMC register is asserted high when the address is programmed.

Figure 35-16. Send Byte Message with and without PEC

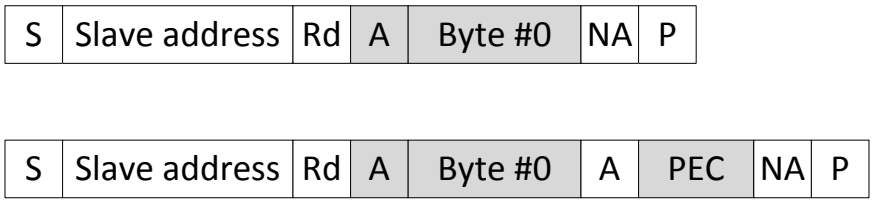


After programming the PMBMC register, the PMBus module transmits the Send Byte message. The firmware can wait for an End of Message interrupt from the PMBus module. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify the slave properly acknowledged the transmitted data.

35.4.2.3 Receive Byte

A Receive Byte message consists of the device address, a single data byte and an optional PEC byte. Data is being read from the slave in a Receive Byte message. To initiate a Receive Byte message, the firmware programs the device address, the R/W bit and the optional PEC_EN into the PMBMC register. The R/W bit is enabled high to indicate a read message type (data transmitted from slave to master).

Figure 35-17. Receive Byte Message with and without PEC

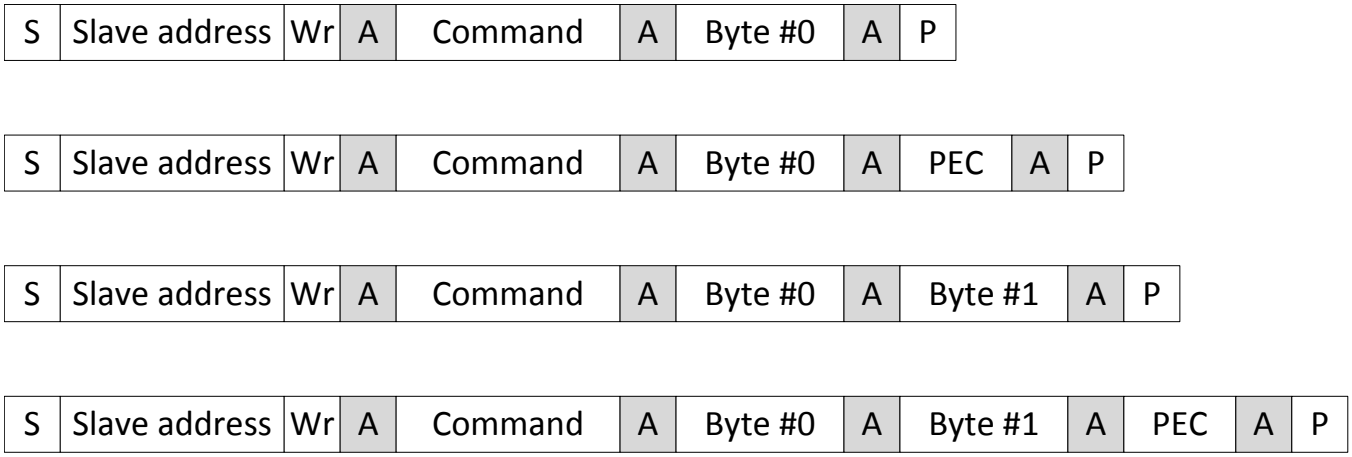


After programming the PMBMC register, the PMBus module transmits the Receive Byte message. The firmware can wait for an End of Message interrupt from the PMBus module to verify the accuracy of the message transmission. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify proper slave acknowledgement of the device address and to determine if any data is available for reading in the PMBRXBUF register. If PEC_EN was asserted in the PMBMC register, the PEC_VALID bit in the PMBSTS register is also checked to ensure a proper PEC byte was received from the slave with the received data.

35.4.2.4 Write Byte/Word

The Write Byte and Write Word messages consist of a device address, a command byte, transmitted data bytes and an optional PEC byte. Write Byte messages include a single byte, while the Write Word messages support transmission of 2 bytes to the corresponding slave module. Similar to the Send Byte protocol, the PMBMC register is configured to send 1 or 2 bytes, the CMD_EN bit is set to enable command byte transmission and the optional PEC_EN bit is set.

Figure 35-18. Write Byte and Write Word Messages with and without PEC



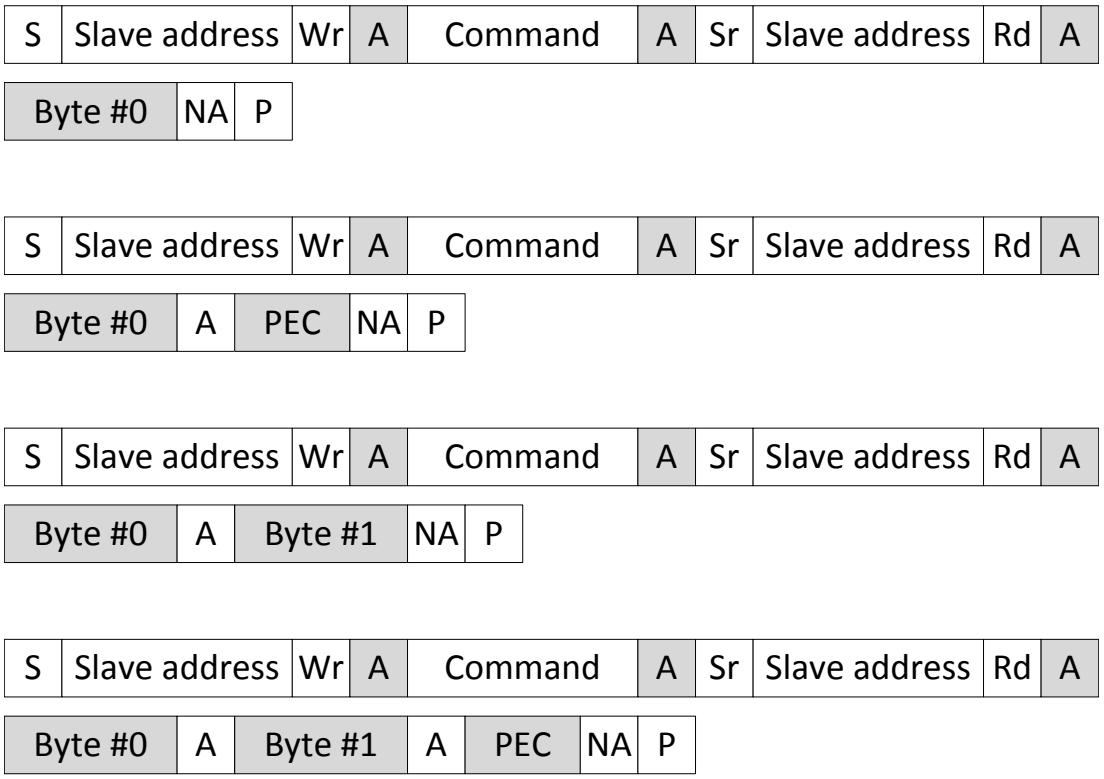
With the command byte transmission enabled, the format of the PMBTXBUF register differs from the Send Byte protocol. In bits 7-0, the firmware must program the command byte to be sent to the slave. The data byte(s) are programmed into bits 15-8 and bits 23-16.

After programming the PMBMC register, the PMBus module transmits the Write Byte/Word message. The firmware can wait for an End of Message interrupt from the module to verify the accuracy of the message transmission. The PMBSTS register indicates if the slave acknowledged the message properly.

35.4.2.5 Read Byte/Word

The Read Byte and Read Word messages consist of a device address, a command byte, received data bytes from a slave and an optional PEC byte. Read Byte messages include a single byte, while the Read Word message protocol supports receipt of 2 bytes from the slave. Similar to the Receive Byte Protocol, the PMBMC register is configured to receive 1 or 2 bytes, the CMD_EN bit is set and the PEC_EN is configured to expect or not expect a PEC byte appended to the message. The PMBus module will automatically terminate the message after the expected number of bytes is received from the slave or if the slave does not properly acknowledge any portion of the message.

Figure 35-19. Read Byte and Read Word Messages with and without PEC

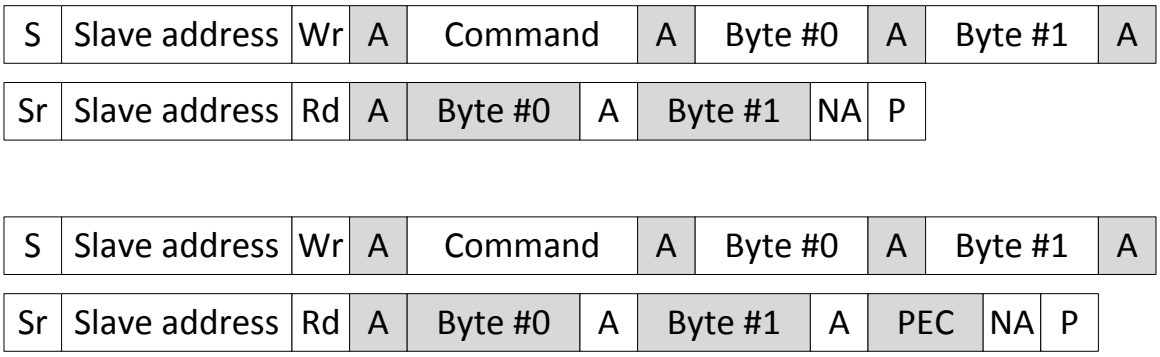


In addition to programming the PMBMC register, the firmware is expected to load the command byte into bits 7-0 of the PMBTXBUF register. Any data received from the slave will be found in the PMBRXBUF register.

35.4.2.6 Process Call

The Process Call protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. A PEC byte can be appended to the read data from the slave as an option to the message protocol. The PMBMC register includes a PRC_CALL bit, which enables the transmission of a Process Call message onto the PMBus. The PMBus module will automatically generate a repeated start condition and initiate the Read Word portion of the message when the process call bit is enabled.

Figure 35-20. Process Call Message with and without PEC



To complete the Write Word portion of the Process Call, the PMBTXBUF register is loaded with the command byte in bits 7-0 and the data bytes are loaded into bits 23-8 of the register.

After programming the PMBMC register, the PMBus module transmits the Process Call Message. The firmware can wait for an End of Message interrupt from the module to determine the validity of the message. Upon the receipt of the EOM, the PMBSTS register should indicate the receipt of 2 bytes from the Read Word portion of the Process Call message and the status of the Slave acknowledgment of the transmit data. If PEC processing is enabled, the PEC_VAL bit within the PMBSTS register indicates the accuracy of the PEC byte received from the slave during the Read Word part of the message.

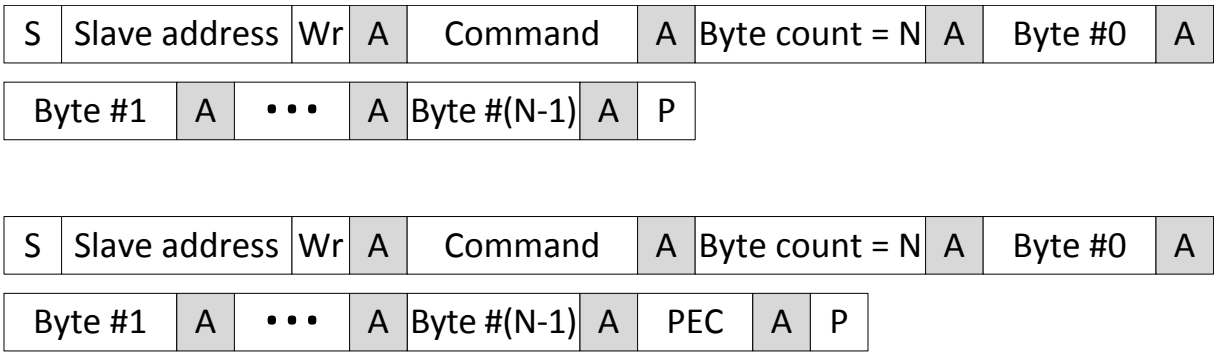
The PRC_CALL bit within the PMBMC register must be disabled for the next non-Process Call message. Please note that any write to the PMBMC register initiates a message, so reconfiguration of the master is not recommended until the firmware requires a new message to be transmitted.

35.4.2.7 Block Write

The Block Write protocol is similar to a Write Word in its structure, with the exception of transmission of more than 2 data bytes in the message. Additionally, the first data byte following the command byte specifies the length of the block of data bytes. As with a majority of the message protocols, the PEC byte can be appended to the end of the write data to the slave.

To initiate a Block Write message on the bus, the PMBMC register is programmed with the block length in the Byte Count bits. The block length is the number of data bytes, excluding the command byte and the first data byte that contains the block length. The PMBus module will automatically insert the block length into the message if the number of data bytes specified by the firmware exceeds 2. The initial write data is loaded into the PMBTXBUF register. With bits 7-0 representing the command byte, the remaining 3 bytes represent the first three data bytes following the block length.

Figure 35-21. Block Write Message with and without PEC



Following programming of the PMBMC register, the Block Write message is transmitted. If the block length exceeds three bytes, the PMBus module will provide a data request interrupt, indicating the need for additional data bytes in the PMBTXBUF register. The PMBus module assumes that if more than 4 bytes are needed to complete the message, the firmware will utilize all 4 bytes when programming the PMBTXBUF register. If less than 4 bytes are needed to finish the Block Write message, the firmware only needs to program the appropriate bits of the PMBTXBUF register.

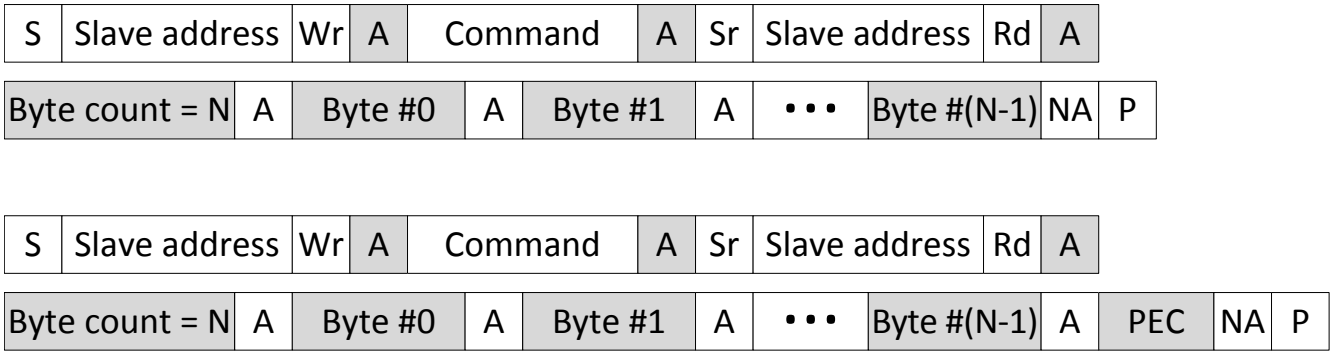
Upon completion of the message, the PMBus module issues an EOM interrupt. The PMBSTS register can be checked to verify the slave accepted the block of write data.

35.4.2.8 Block Read

The Block Read protocol is similar to a Read Word in its structure, with the exception that there are more than 2 data bytes received from the slave. The first data byte transmitted by the slave represents the block length of the data being written by the slave. If PEC processing is enabled, the slave appends a PEC byte to the end of the message.

To initiate a Block Read message on the PMBus, the PMBMC register is programmed with the block length in the Byte Count bits. This count excludes the command byte, any slave address and the block length bytes in the message. The command byte to be transmitted to the slave is written into bits 7-0 of the PMBTXBUF register prior to the programming of the PMBMC register.

Figure 35-22. Block Read Message with and without PEC

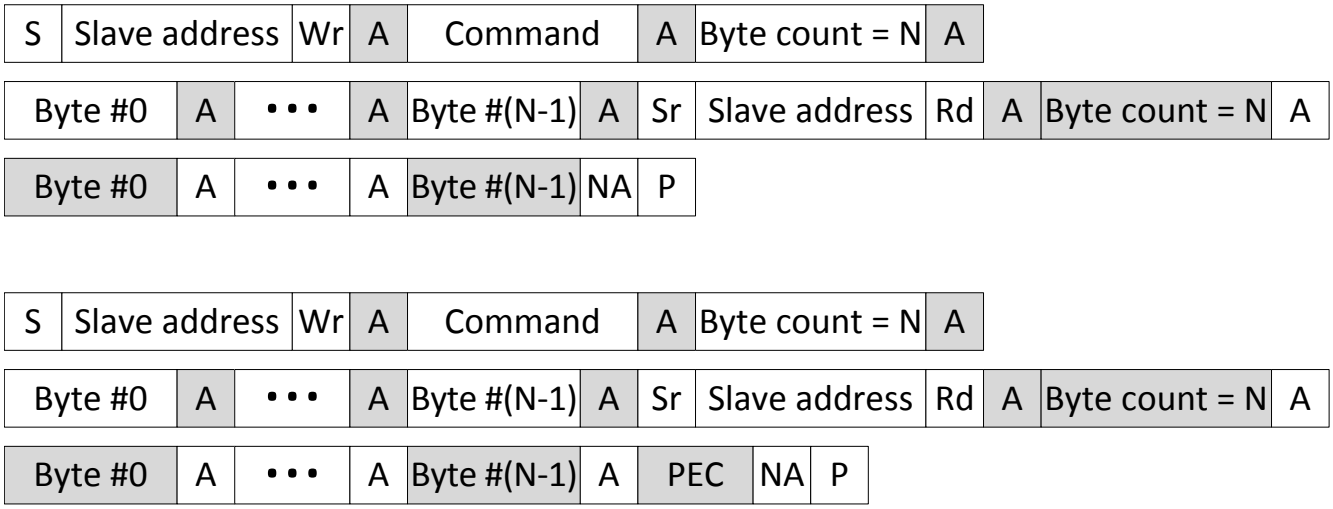


After configuring the PMBMC register, the Block Read message is transmitted. The module interrupts the firmware upon receipt of 4 data bytes from the slave. If the block length is 3, the EOM interrupt will be received concurrently with the data ready interrupt. Otherwise, only a data ready interrupt is asserted, indicating 4 bytes are ready for reading by the firmware. At the end of the message, less than 4 bytes may be stored in the PMBRXBUF register. The RX Byte Count bits in the PMBSTS register indicate the number of bytes available in the final data transfer. The firmware may verify the received PEC upon detection of the End of Message interrupt.

35.4.2.9 Block Write-Block Read Process Call

The Block Read-Block Write Process Call protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The operation of the master is similar to a Block Write operation. Loading the block length into the byte count bits of the PMBMC register provides the length of the Block Write portion of the message. In addition, the PRC_CALL bit within the PMBMC register must be enabled. Upon completion of the Block Write part of the message, the PMBus module will automatically issue a Repeated Start condition on the PMBus and start transmission of the Block Read portion of the message. Operation of the PMBus module after the Repeated Start condition is the same as it would be in a simple Block Read Message.

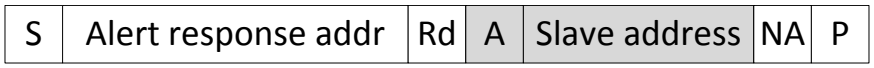
Figure 35-23. Block Write-Block Read Process Call Message with and without PEC



35.4.2.10 Alert Response

The Alert Response Message is utilized when the master detects an alert condition from a slave. In master mode, the Alert Response Message is simply a Receive Byte message with PEC disable and the slave address set to 0xC (Alert Response address). The PMBus module detects the alert condition on an input and interrupts the firmware indicating the assertion of an alert condition (slave desires to communicate with master). Programming the PMBMC register with the Alert Response address initiates the Alert Response message and provides the device address of the slave requesting service. The device address will be found in the PMBRXBUF register following receipt of the EOM interrupt.

Figure 35-24. Alert Response Message



35.4.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. By asserting the EXT_CMD bit within the PMBMC register, two command bytes are transmitted on the message protocol. Extended commands can be added to the Read Byte, Read Word, Write Byte and Write Word protocols. Operation of the PMBus module in extended command mode is similar to these formats. In programming the write data or first part of the read message, the second command byte is loaded into bits 15-8 of the PMBTXBUF register with the remaining data bytes. The remaining operation of the module is identical to the previous protocols, except for the inclusion of a Repeated Start condition and slave address in the write messages. No support is required by firmware for these additional bytes in the write messages. The module will interpret the EXT_CMD bit and make the appropriate format changes.

Figure 35-25. Extended Command Write Message with and without PEC

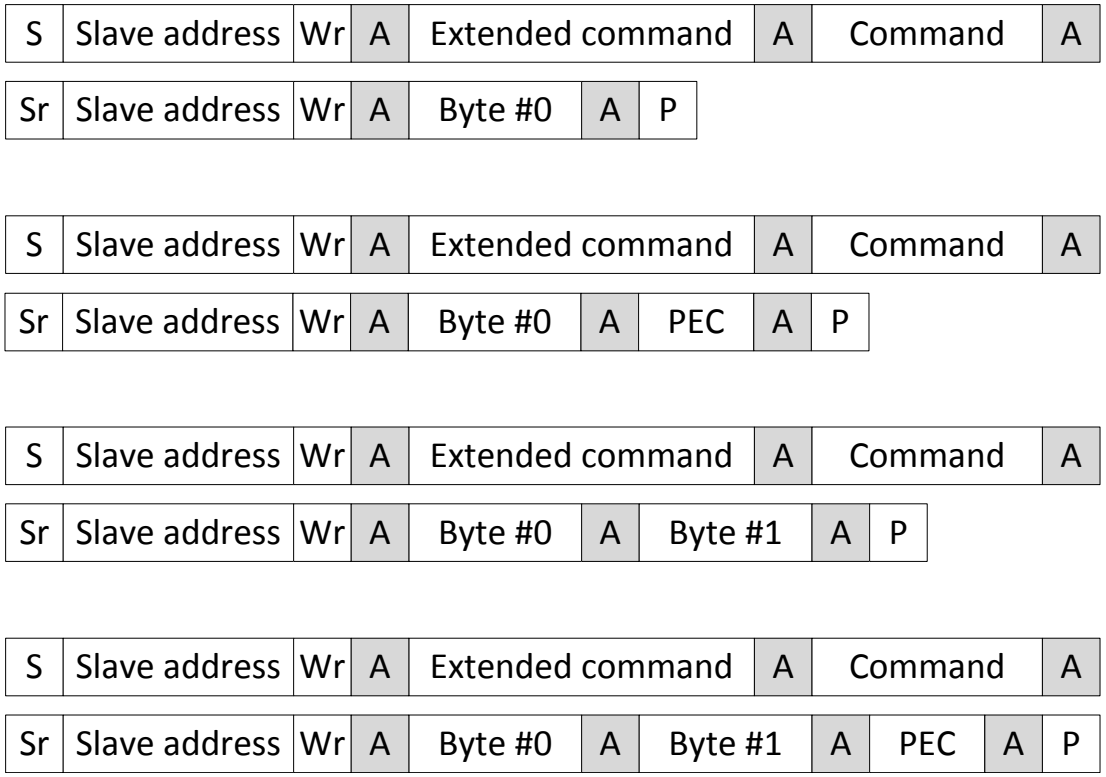


Figure 35-26. Extended Command Read Message with and without PEC

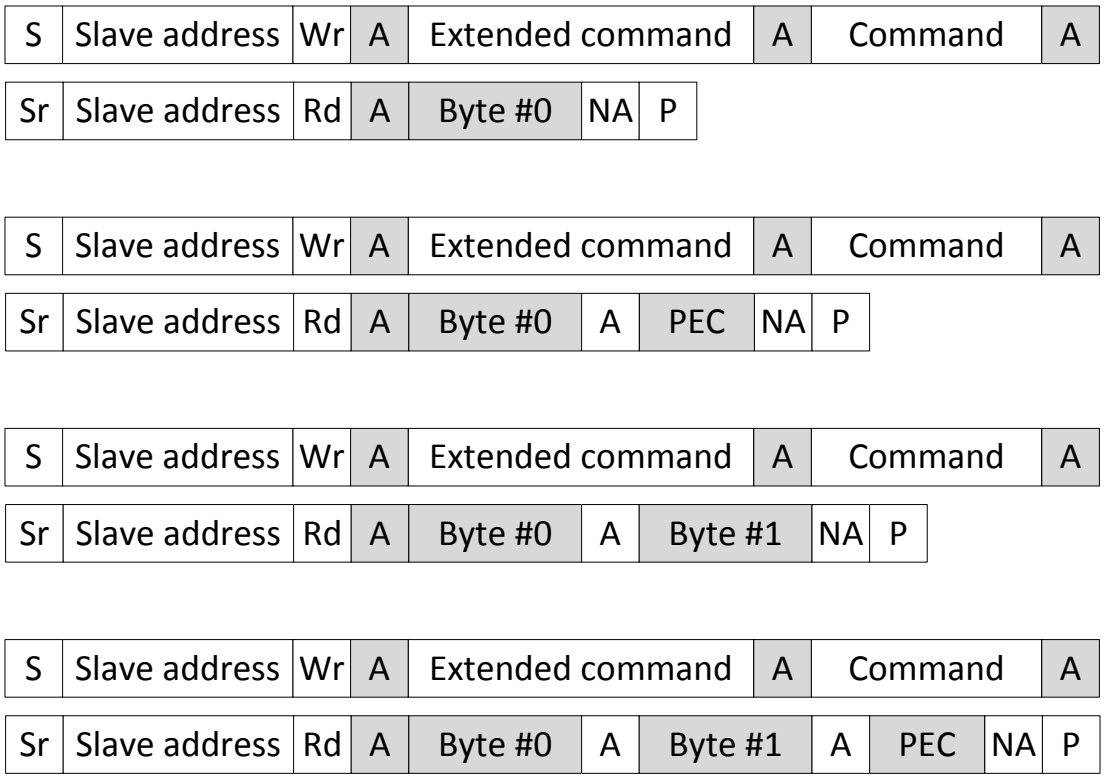
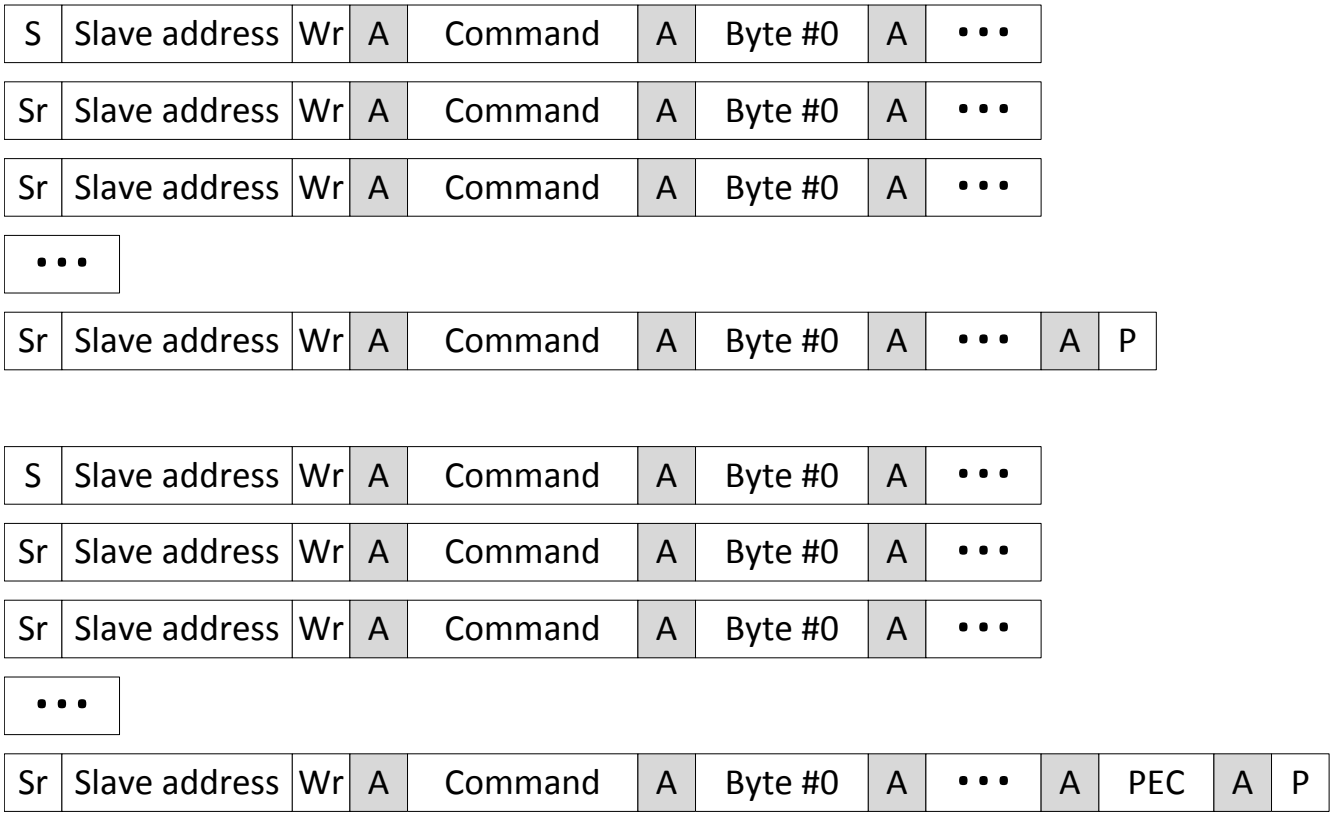


35.4.2.12 Group Command

The Group Command Protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. To initiate a Group Command, the GRP_CMD bit within the PMBMC register must be set when programming the slave address for the first device in the message. The rest of the message is processed as a write byte/word message. At the conclusion of the first part of the Group Command message, the firmware programs the next device address in the PMBMC register. The PMBus module will send a repeated start on the bus and begin the next part of the message. When programming the last device address of the Group Command message, the firmware must disable the GRP_CMD bit when programming the PMBMC register.

Figure 35-27. Group Command Message with and without PEC



35.5 PMBus Registers

This section describes the Power-Management Bus module Registers.

35.5.1 PMBus Base Addresses

Table 35-1. PMBUS Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
PmbusaRegs	PMBUS_REGS	PMBUSA_BASE	0x0000_6400	YES	YES	YES	YES	YES

35.5.2 PMBUS_REGS Registers

Table 35-2 lists the PMBUS_REGS registers. All register offset addresses not listed in Table 35-2 should be considered as reserved locations and the register contents should not be modified.

Table 35-2. PMBUS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	PMBMC	PMBUS Master Mode Control Register	EALLOW	Go
2h	PMBTXBUF	PMBUS Transmit Buffer		Go
4h	PMBRXBUF	PMBUS Receive buffer		Go
6h	PMBACK	PMBUS Acknowledge Register		Go
8h	PMBSTS	PMBUS Status Register		Go
Ah	PMBINTM	PMBUS Interrupt Mask Register	EALLOW	Go
Ch	PMBSC	PMBUS Slave Mode Configuration Register	EALLOW	Go
Eh	PMBHSA	PMBUS Hold Slave Address Register		Go
10h	PMBCTRL	PMBUS Control Register	EALLOW	Go
12h	PMBTIMCTL	PMBUS Timing Control Register	EALLOW	Go
14h	PMBTIMCLK	PMBUS Clock Timing Register	EALLOW	Go
16h	PMBTIMSTSETUP	PMBUS Start Setup Time Register	EALLOW	Go
18h	PMBTIMBIDLE	PMBUS Bus Idle Time Register	EALLOW	Go
1Ah	PMBTIMLOWTIMOUT	PMBUS Clock Low Timeout Value Register	EALLOW	Go
1Ch	PMBTIMHIGHTIMOUT	PMBUS Clock High Timeout Value Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 35-3 shows the codes that are used for access types in this section.

Table 35-3. PMBUS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

35.5.2.1 PMBMC Register (Offset = 0h) [reset = 0h]

PMBMC is shown in Figure 35-28 and described in Table 35-4.

Return to the Summary Table.

PMBUS Master Mode Control Register

Table 35-10. PMBSC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-21	RX_BYTE_ACK_CNT	R/W	3h	Configures number of data bytes to automatically acknowledge when receiving data in slave mode. 00 = 1 byte received by slave. Firmware is required to manually acknowledge every received byte. 01 = 2 bytes received by slave. Hardware automatically acknowledges the first received byte. Firmware is required to manually acknowledge after the second received byte. 10 = 3 bytes received by slave. Hardware automatically acknowledges the first 2 received bytes. Firmware is required to manually acknowledge after the third received byte. 11 = 4 bytes received by slave. Hardware automatically acknowledges the first 3 received bytes. Firmware is required to manually acknowledge after the fourth received byte Reset type: SYSRSn
20	MAN_CMD	R/W	0h	0 = Slave automatically acknowledges received command code 1 = Data Request flag generated after receipt of command code, firmware required to issue ACK to continue message Reset type: SYSRSn
19	TX_PEC	R/W	0h	Asserted when the slave needs to send a PEC byte at end of message. PMBus Interface will transmit the calculated PEC byte after transmitting the number of data bytes indicated by TX Byte Cnt(Bits 18:16). Reset type: SYSRSn

Table 35-10. PMBSC Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18-16	TX_COUNT	R/W	0h	0 = No bytes valid 1 = One byte valid, Byte #0 (Bits 7:0 of Transmit Data Register) 2 = Two bytes valid, Bytes #0 and #1 (Bits 15:0 of Transmit Data Register) 3 = Three bytes valid, Bytes #0-2 (Bits 23:0 of Transmit Data Register) 4 = Four bytes valid, Bytes #0-3 (Bits 31:0 of Transmit Data Register) Reset type: SYSRSn
15	PEC_ENA	R/W	0h	0 = PEC processing disabled 1 = PEC processing enabled Reset type: SYSRSn
14-8	SLAVE_MASK	R/W	7Fh	Used in address detection, the slave mask enables acknowledgement of multiple device addresses by the slave. Writing a '0' to a bit within the slave mask enables the corresponding bit in the slave address to be either '1' or '0' and still allow for a match. Writing a '0' to all bits in the mask enables the PMBus Interface to acknowledge any device address. Upon power-up, the slave mask defaults to 7Fh, indicating the slave will only acknowledge the address programmed into the Slave Address (Bits 6-0). Reset type: SYSRSn
7	MAN_SLAVE_ACK	R/W	0h	0 = Slave automatically acknowledges device address specified in SLAVE_ADDR, Bits 6:0 1 = Enables the Manual Slave Address Acknowledgement Mode. Firmware is required to read received address and acknowledge on every message Note: When bit 31 (I2C_mode) of PMBCTRL register is set it is recommended to use manual acknowledging of slave address only (MAN_SLAVE_ACK =1). Reset type: SYSRSn
6-0	SLAVE_ADDR	R/W	7Ch	Configures the current device address of the slave. Used in automatic slave address acknowledge mode (default mode). The PMBus Interface will compare the received device address with the value stored in the Slave Address bits and the mask configured in the Slave Mask bits. If matching, the slave will acknowledge the device address. Reset type: SYSRSn

35.5.2.8 PMBHSA Register (Offset = Eh) [reset = 0h]

PMBHSA is shown in Figure 35-35 and described in Table 35-11.

Return to the Summary Table.

Serial Communications Interface (SCI)

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two−wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a 16-level deep FIFO for reducing servicing overhead, and each has its own separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

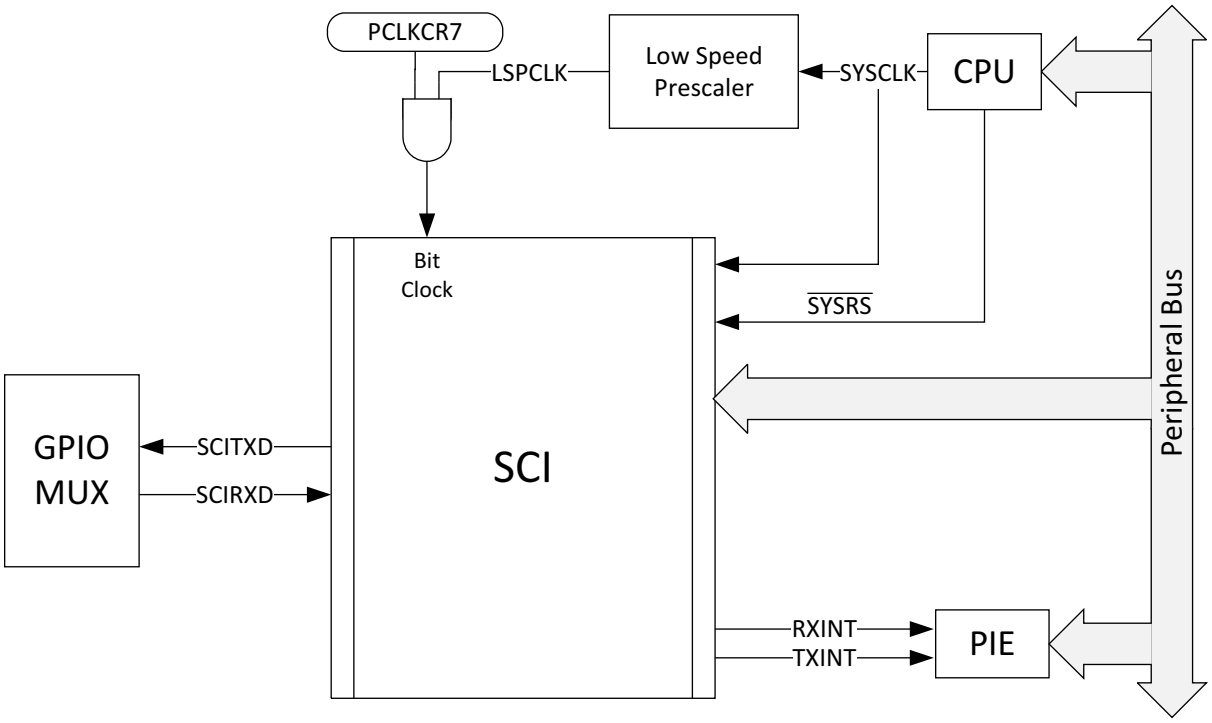
To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

Topic **Page**

36.1 Introduction

The SCI interfaces are shown in Figure 36-1.

Figure 36-1. SCI CPU Interface



Features of the SCI module include:

- Two external pins:
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin

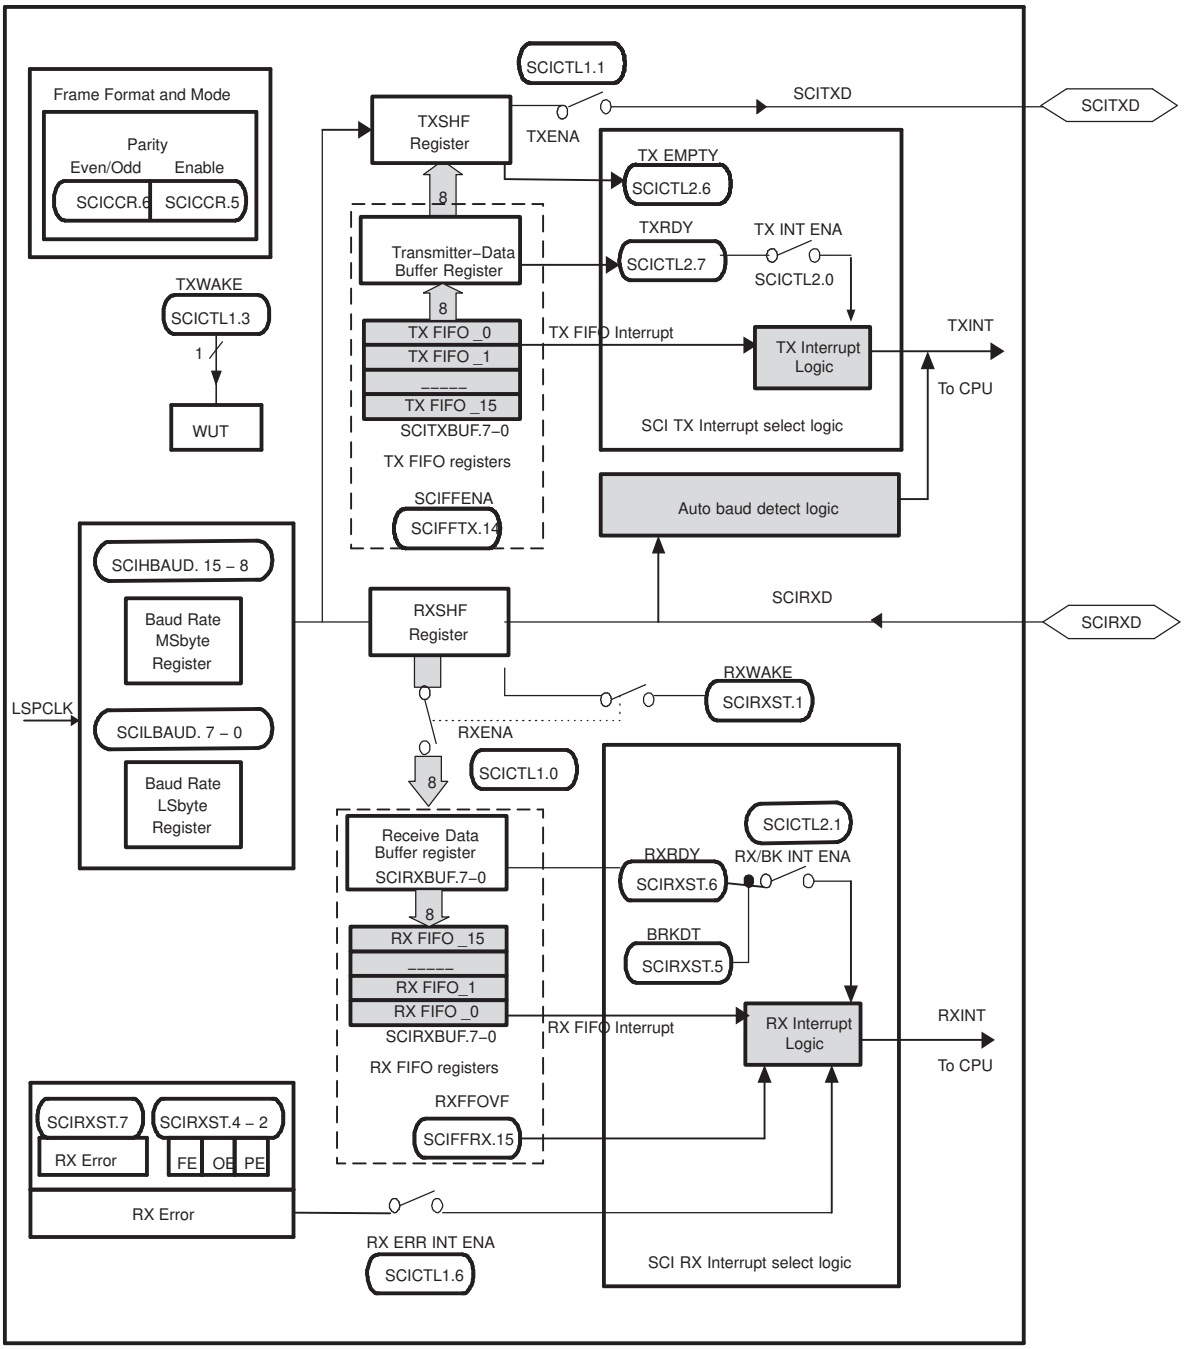
  Both pins can be used as GPIO if not used for SCI.
- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)
- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags.
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- 16-level transmit/receive FIFO

Figure 36-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in Section 36.14 of this chapter.

Figure 36-2. Serial Communications Interface (SCI) Module Block Diagram



36.2 Architecture

The major elements used in full-duplex operation are shown in Figure 36-2 and include:

- A transmitter (TX) and its major registers (upper half of Figure 36-2)
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and its major registers (lower half of Figure 36-2)
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

36.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in Table 36-1.

Table 36-1. SCI Module Signal Summary

Signal Name	Description
	External signals
SCIRXD	SCI Asynchronous Serial Port receive data
SCITXD	SCI Asynchronous Serial Port transmit data
	Control
Baud clock	LSPCLK Prescaled clock
	Interrupt signals
TXINT	Transmit interrupt
RXINT	Receive Interrupt

36.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

36.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see Section 36.8) and the address-bit multiprocessor mode (see Section 36.9). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see Section 36.10) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits

- An even/odd parity bit or no parity bit
- One or two stop bits

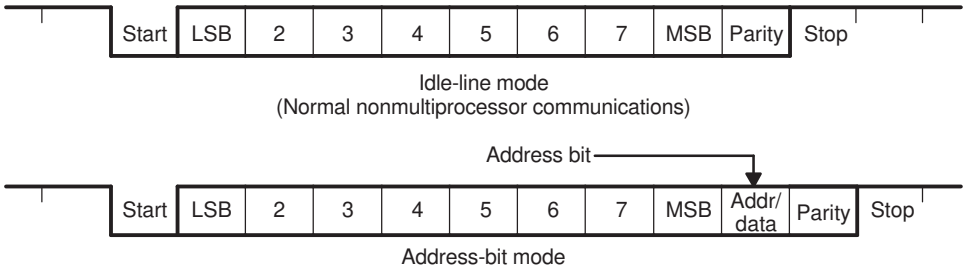
36.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in Figure 36-3, consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with its formatting information is called a frame and is shown in Figure 36-3.

Figure 36-3. Typical SCI Data Frame Formats



To program the data format, use the SCICCR register. The bits used to program the data format are shown in Table 36-2.

Table 36-2. Programming the Data Format Using SCICCR

Bit(s)	Bit Name	Designation	Functions
2-0	SCI CHAR2-0	SCICCR.2:0	Select the character (data) length (one to eight bits).
5	PARITY ENABLE	SCICCR.5	Enables the parity function if set to 1, or disables the parity function if cleared to 0.
6	EVEN/ODD PARITY	SCICCR.6	If parity is enabled, selects odd parity if cleared to 0 or even parity if set to 1.
7	STOP BITS	SCICCR.7	Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1.

36.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there should be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that they are interrupted only when the address byte is detected. When a processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, it does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

36.7.1 Recognizing the Address Byte

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode (Section 36.8) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than ten bytes of data. The idle-line mode should be used for typical non-multiprocessor SCI communication.
- The address-bit mode (Section 36.9) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, it does not have to wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

36.7.2 Controlling the SCI TX and RX Features

The multiprocessor mode is software selectable via the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

36.7.3 Receipt Sequence

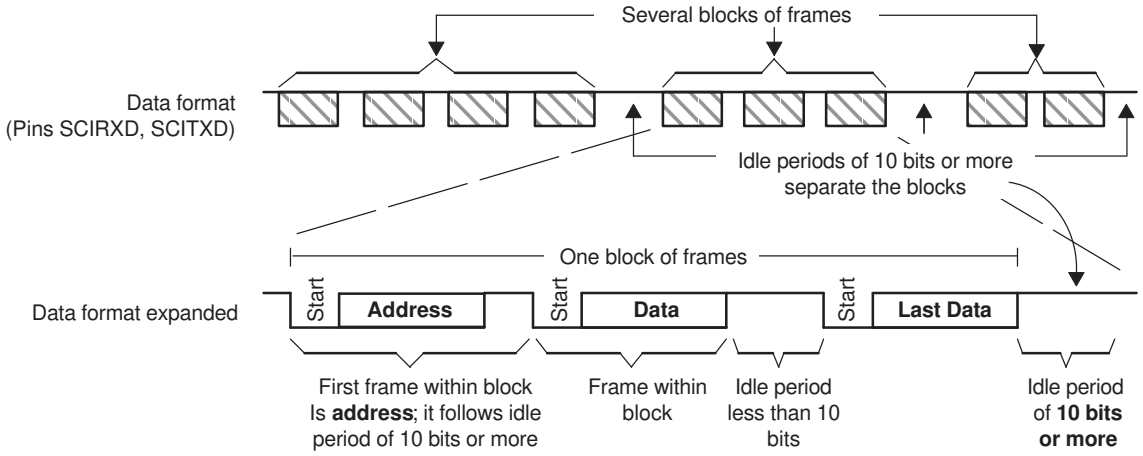
In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt). It reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against its device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

36.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit=0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 36-4 (ADDR/IDLE MODE bit is bit 3 of SCICCR).

Figure 36-4. Idle-Line Multiprocessor Communication Format



36.8.1 Idle-Line Mode Steps

The steps followed by the idle-line mode:

Step 1. SCI wakes up after receipt of the block-start signal.

Step 2. The processor recognizes the next SCI interrupt.

Step 3. The interrupt service routine compares the received address (sent by a remote transmitter) to its own.

Step 4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.

Step 5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute its main program without being interrupted by the SCI port until the next detection of a block start.

36.8.2 Block Start Signal

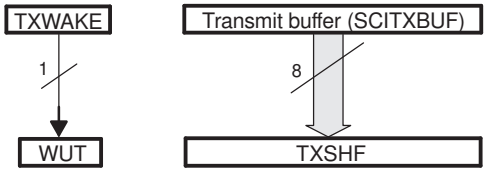
There are two ways to send a block-start signal:

1. **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
2. **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

36.8.3 Wake-UP Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in Figure 36-5.

Figure 36-5. Double-Buffered WUT and TXSHF



36.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don’t care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

   Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.
3. **Write a new address value to SCITXBUF**

   A don’t-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don’t-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE if necessary) can be written to again because TXSHF and WUT are both double-buffered.

36.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does it request a receive interrupt until an address frame is detected.

36.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit=1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 36-6).

36.9.1 Sending an Address

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

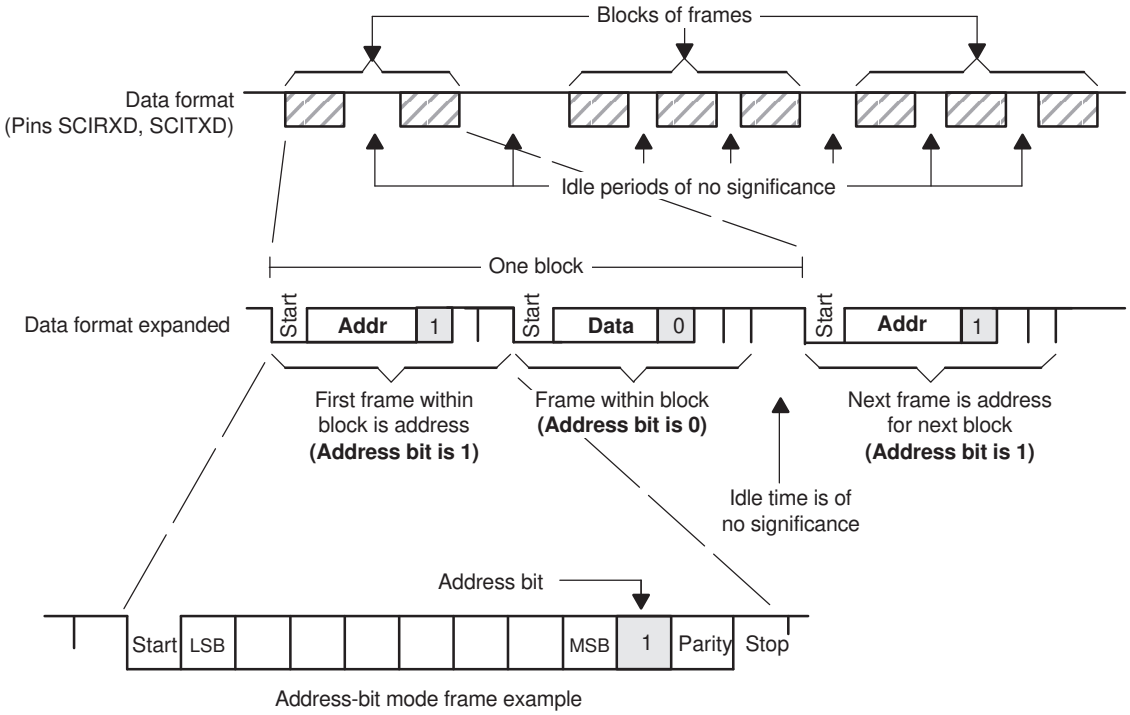
1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

When this address value is transferred to the TXSHF register and shifted out, its address bit is sent as a 1. This flags the other processors on the serial link to read the address.

2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

NOTE: As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

Figure 36-6. Address-Bit Multiprocessor Communication Format



36.10 SCI Communication Format

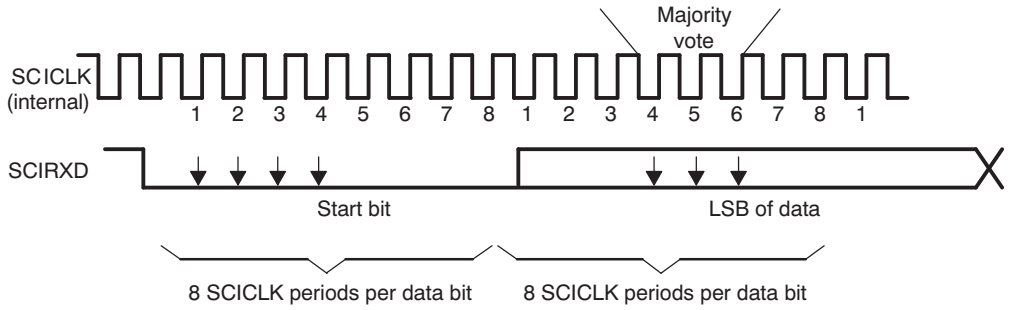
The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 36-7). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 36-7. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 36-7 illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes itself to frames, the external transmitting and receiving devices do not have to use a synchronized serial clock. The clock can be generated locally.

Figure 36-7. SCI Asynchronous Communications Format

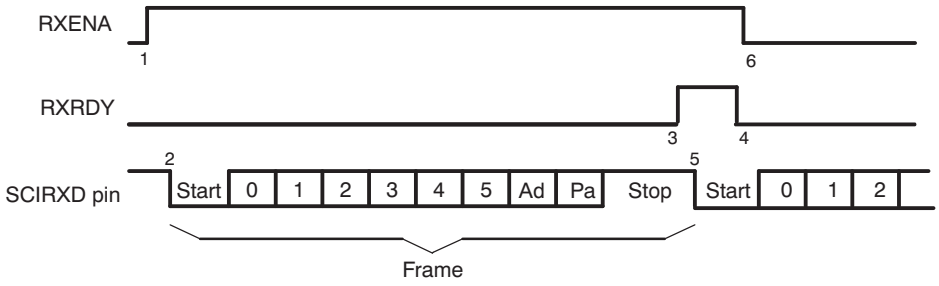


36.10.1 Receiver Signals in Communication Modes

Figure 36-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

Figure 36-8. SCI RX Signals in Communication Modes



(1) Data arrives on the SCIRXD pin, start bit detected.

(2) Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

Notes:

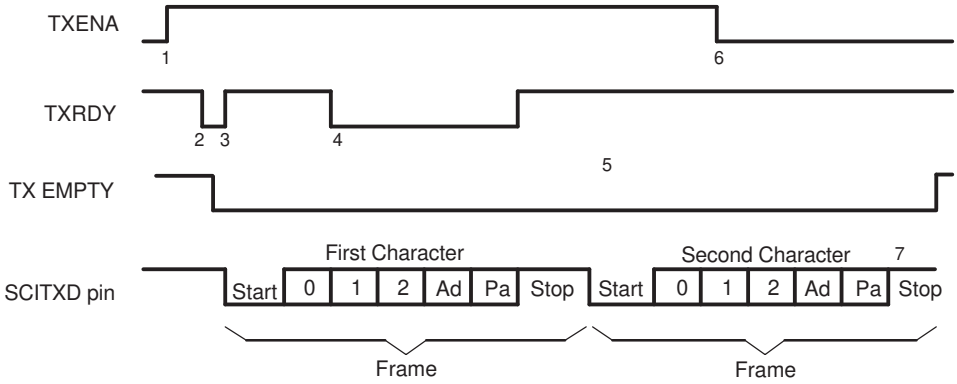
1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

36.10.2 Transmitter Signals in Communication Modes

Figure 36-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

Figure 36-9. SCI TX Signals in Communications Mode



Notes:

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and it requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

36.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag which is a logical OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits which are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the peripheral interrupt expansion controller section of the *External Peripheral Interface (ePIE)* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for ten bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

NOTE: Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

36.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. Table 36-3 shows the baud-select values for common SCI bit rates.

Table 36-3. Asynchronous Baud Register Values for Common SCI Bit Rates

		LSPCLK Clock Frequency, 100 MHz	
Ideal Baud	**BRR**	**Actual Baud**	**% Error**
2400	5207 (1457h)	2400	0
4800	2603 (A2Bh)	4800	0
9600	1301 (515h)	9601	0.01
19200	650 (28Ah)	19201	0.01
38400	324 (144h)	38462	0.16

LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100MHz, then the maximum baud rate is 6.25Mbps.

36.13 SCI Enhanced Features

The 28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

36.13.1 SCI FIFO Description

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. *Reset.* At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. *Standard SCI.* The standard SCI modes will work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. *FIFO enable.* FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of its operation.
4. Active registers. All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. *Interrupts.* FIFO mode has two interrupts; one for transmit FIFO, TXINT and one for receive FIFO, RXINT. RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI will be disabled and this interrupt will service as SCI transmit FIFO interrupt.
6. *Buffers.* Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8 bits wide and receive FIFO registers are 10 bits wide. The one-word transmit buffer of the standard SCI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from the transmit FIFO only after the last bit of the shift register is shifted out. With the FIFO enabled, TXSHF is directly loaded after an optional delay value (SCIFFCT), TXBUF is not used. When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. *Delayed transfer.* The rate at which words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define

a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.

8. *FIFO status bits.* Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12−8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to one.
9. *Programmable interrupt levels.* Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12−8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4−0). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits will be 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

Figure 36-10 and Table 36-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

Figure 36-10. SCI FIFO Interrupt Flags and Enable Logic

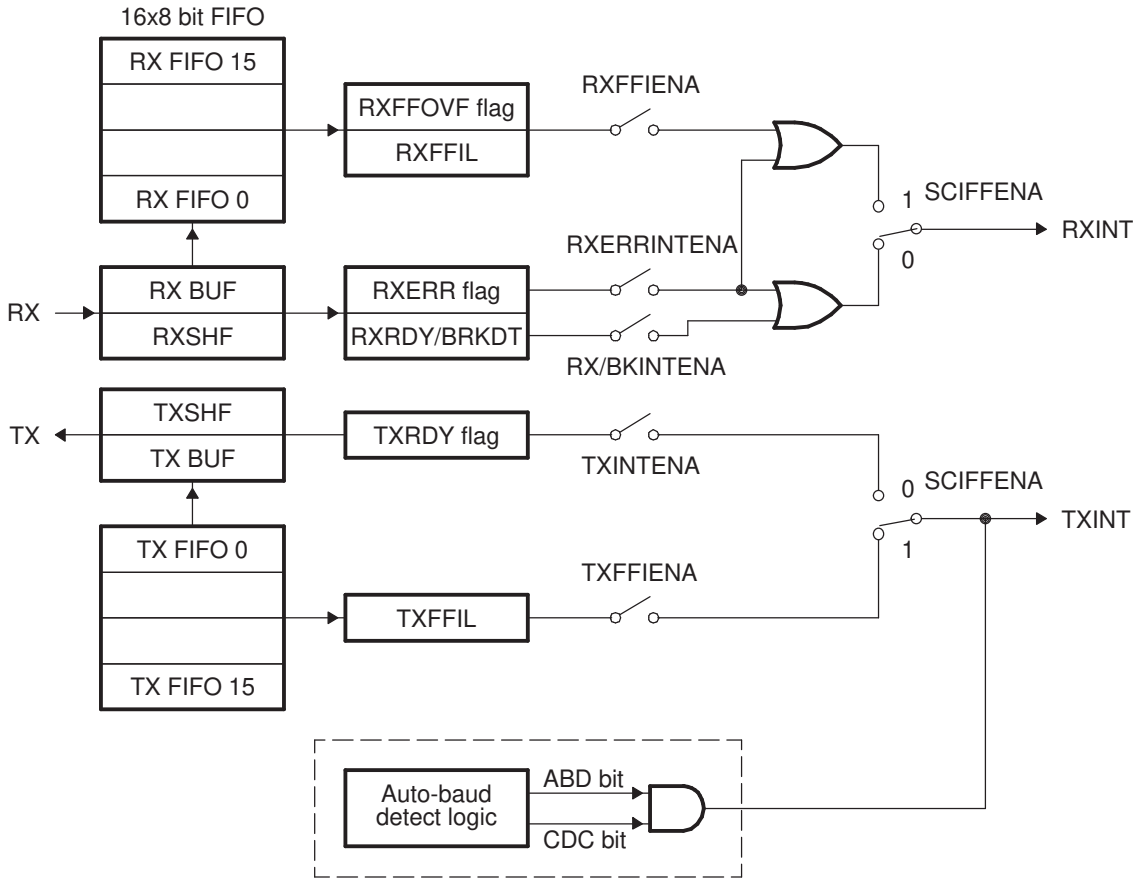


Table 36-4. SCI Interrupt Flags

FIFO Options[1]	SCI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable SCIFFENA	Interrupt Line
SCI without FIFO	Receive error	RXERR [2]	RXERRINTENA	0	RXINT
	Receive break	BRKDT	RX/BKINTENA	0	RXINT
	Data receive	RXRDY	RX/BKINTENA	0	RXINT
	Transmit empty	TXRDY	TXINTENA	0	TXINT
SCI with FIFO	Receive error and receive break	RXERR	RXERRINTENA	1	RXINT
	FIFO receive	RXFFIL	RXFFIENA	1	RXINT
	Transmit empty	TXFFIL	TXFFIENA	1	TXINT
Auto-baud	Auto-baud detected	ABD	Don't care	x	TXINT

(1) FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.
(2) RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag

36.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

36.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit should be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt will occur (TXINT). After the interrupt service CDC bit has to be cleared by software. If CDC remains set even after interrupt service, there should be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (Bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500 Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud- detect hardware will detect the incoming baud rate and set the ABD bit.
4. The auto-detect hardware will update the baud rate register with the equivalent baud value hex. The logic will also generate an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt will occur (TXINT). After the interrupt service CDC bit must be cleared by software.

NOTE: At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications may work well, this slew rate may limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and 28x SCI boot loader using a lower baud rate.
- The host may then handshake with the loaded 28x application to set the SCI baud rate register to the desired higher baud rate.

36.14 SCI Registers

The section describes the Serial Communication Interface module Registers.

36.14.1 SCI Base Addresses

Table 36-5. SCI Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
SciaRegs	SCI_REGS	SCIA_BASE	0x0000_7200	YES	YES	-	-	YES
ScibRegs	SCI_REGS	SCIB_BASE	0x0000_7210	YES	YES	-	-	YES
ScicRegs	SCI_REGS	SCIC_BASE	0x0000_7220	YES	YES	-	-	YES
ScidRegs	SCI_REGS	SCID_BASE	0x0000_7230	YES	YES	-	-	YES

36.14.2 SCI_REGS Registers

Table 36-6 lists the SCI_REGS registers. All register offset addresses not listed in Table 36-6 should be considered as reserved locations and the register contents should not be modified.

Table 36-6. SCI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SCICCR	Communications control register		Go
1h	SCICTL1	Control register 1		Go
2h	SCIHBAUD	Baud rate (high) register		Go
3h	SCILBAUD	Baud rate (low) register		Go
4h	SCICTL2	Control register 2		Go
5h	SCIRXST	Receive status register		Go
6h	SCIRXEMU	Receive emulation buffer register		Go
7h	SCIRXBUF	Receive data buffer		Go
9h	SCITXBUF	Transmit data buffer		Go
Ah	SCIFFTX	FIFO transmit register		Go
Bh	SCIFFRX	FIFO receive register		Go
Ch	SCIFFCT	FIFO control register		Go
Fh	SCIPRI	SCI priority control		Go

Complex bit access types are encoded to fit into small table cells. Table 36-7 shows the codes that are used for access types in this section.

Table 36-7. SCI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

36.14.2.1 SCICCR Register (Offset = 0h) [reset = 0h]

SCICCR is shown in Figure 36-11 and described in Table 36-8.

Return to the Summary Table.

SCICCR defines the character format, protocol, and communications mode used by the SCI.

Figure 36-11. SCICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
STOPBITS	PARITY	PARITYENA	LOOPBKENA	ADDRIDLE_MODE	SCICHAR		
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h		

Table 36-8. SCICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	STOPBITS	R/W	0h	SCI number of stop bits. This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit. Reset type: SYSRSn 0h (R/W) = One stop bit 1h (R/W) = Two stop bits
6	PARITY	R/W	0h	SCI parity odd/even selection. If the PARITY ENABLE bit (SCICCR, bit 5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters). Reset type: SYSRSn 0h (R/W) = Odd parity 1h (R/W) = Even parity
5	PARITYENA	R/W	0h	SCI parity enable. This bit enables or disables the parity function. If the SCI is in the addressbit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation. Reset type: SYSRSn 0h (R/W) = Parity disabled no parity bit is generated during transmission or is expected during reception 1h (R/W) = Parity is enabled
4	LOOPBKENA	R/W	0h	Loop Back test mode enable. This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin. Reset type: SYSRSn 0h (R/W) = Loop Back test mode disabled 1h (R/W) = Loop Back test mode enabled
3	ADDRIDLE_MODE	R/W	0h	SCI multiprocessor mode control bit. This bit selects one of the multiprocessor protocols.Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1, bit 2 and SCICTL1, bit 3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications. Reset type: SYSRSn 0h (R/W) = Idle-line mode protocol selected 1h (R/W) = Address-bit mode protocol selected

Table 36-8. SCICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	SCICHAR	R/W	0h	Character-length control bits 2-0. These bits select the SCI character length from one to eight bits. Characters of less than eight bits are right-justified in SCIRXBUF and SCIRXEMU and are padded with leading zeros in SCIRXBUF. SCITXBUF doesn't need to be padded with leading zeros. Reset type: SYSRSn 0h (R/W) = SCICHAR_LENGTH_1 1h (R/W) = SCICHAR_LENGTH_2 2h (R/W) = SCICHAR_LENGTH_3 3h (R/W) = SCICHAR_LENGTH_4 4h (R/W) = SCICHAR_LENGTH_5 5h (R/W) = SCICHAR_LENGTH_6 6h (R/W) = SCICHAR_LENGTH_7 7h (R/W) = SCICHAR_LENGTH_8

36.14.2.2 SCICTL1 Register (Offset = 1h) [reset = 0h]

SCICTL1 is shown in Figure 36-12 and described in Table 36-9.

Return to the Summary Table.

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

Figure 36-12. SCICTL1 Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED	RXERRINTENA	SWRESET	RESERVED	TXWAKE	SLEEP	TXENA	RXENA

Table 36-9. SCICTL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RXERRINTENA	R/W	0h	SCI receive error interrupt enable. Setting this bit enables an interrupt if the RX ERROR bit (SCIRXST, bit 7) becomes set because of errors occurring. Reset type: SYSRSn 0h (R/W) = Receive error interrupt disabled 1h (R/W) = Receive error interrupt enabled
5	SWRESET	R/W	0h	SCI software reset (active low). Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. The SW RESET bit does not affect any of the configuration bits. All affected logic is held in the specified reset state until a 1 is written to SW RESET (the bit values following a reset are shown beneath each register diagram in this section). Thus, after a system reset, re-enable the SCI by writing a 1 to this bit. Clear this bit after a receiver break detect (BRKDT flag, bit SCIRXST, bit 5). SW RESET affects the operating flags of the SCI, but it neither affects the configuration bits nor restores the reset values. Once SW RESET is asserted, the flags are frozen until the bit is deasserted. The affected flags are as follows: Value After SW SCI Flag Register Bit RESET 1 TXRDY SCICTL2, bit 7 1 TX EMPTY SCICTL2, bit 6 0 RXWAKE SCIRXST, bit 1 0 PE SCIRXST, bit 2 0 OE SCIRXST, bit 3 0 FE SCIRXST, bit 4 0 BRKDT SCIRXST, bit 5 0 RXRDY SCIRXST, bit 6 0 RX ERROR SCIRXST, bit 7 Reset type: SYSRSn 0h (R/W) = Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. 1h (R/W) = After a system reset, re-enable the SCI by writing a 1 to this bit.
4	RESERVED	R	0h	Reserved

Table 36-9. SCICTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	TXWAKE	R/W	0h	SCI transmitter wake-up method select. The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3) Reset type: SYSRSn 0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1 1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5) it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.
2	SLEEP	R/W	0h	SCI sleep. The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode. The receiver still operates when the SLEEP bit is set however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected. Reset type: SYSRSn 0h (R/W) = Sleep mode disabled 1h (R/W) = Sleep mode enabled
1	TXENA	R/W	0h	SCI transmitter enable. Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later. Reset type: SYSRSn 0h (R/W) = Transmitter disabled 1h (R/W) = Transmitter enabled
0	RXENA	R/W	0h	SCI receiver enable. Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers). Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, the receiver shift register can continue to assemble characters. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF. Reset type: SYSRSn 0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers 1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF

36.14.2.3 SCIHBAUD Register (Offset = 2h) [reset = 0h]

SCIHBAUD is shown in Figure 36-13 and described in Table 36-10.

Return to the Summary Table.

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Figure 36-13. SCIHBAUD Register

15-8	RESERVED	R	0h	Reserved
7-0	BAUD	R/W	0h	SCI 16-bit baud selection Registers SCIHBAUD (MSbyte). The internally-generated serial clock is determined by the low speed peripheral clock (LSPCLK) signal and the two baud-select registers. The SCI uses the 16-bit value of these registers to select one of 64K serial clock rates for the communication modes. BRR = (SCIHBAUD << 8) + (SCILBAUD) The SCI baud rate is calculated using the following equation: SCI Asynchronous Baud = LSPCLK / ((BRR + 1) *8) Alternatively, BRR = LSPCLK / (SCI Asynchronous Baud * 8) - 1 Note that the above formulas are applicable only when 0 < BRR < 65536. If BRR = 0, then SCI Asynchronous Baud = LSPCLK / 16 Where: BRR = the 16-bit value (in decimal) in the baud-select registers Reset type: SYSRSn

36.14.2.4 SCILBAUD Register (Offset = 3h) [reset = 0h]

SCILBAUD is shown in Figure 36-14 and described in Table 36-11.

Return to the Summary Table.

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Table 36-12. SCICTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	TXRDY	R	1h	Transmitter buffer register ready flag. When set, this bit indicates that the transmit data buffer register, SCITXBUF, is ready to receive another character. Writing data to the SCITXBUF automatically clears this bit. When set, this flag asserts a transmitter interrupt request if the interrupt-enable bit, TX INT ENA (SCICTL2.0), is also set. TXRDY is set to 1 by enabling the SW RESET bit (SCICTL1.5) or by a system reset. Reset type: SYSRSn 0h (R/W) = SCITXBUF is full 1h (R/W) = SCITXBUF is ready to receive the next character
6	TXEMPTY	R	1h	Transmitter empty flag. This flag's value indicates the contents of the transmitter's buffer register (SCITXBUF) and shift register (TXSHF). An active SW RESET (SCICTL1.5), or a system reset, sets this bit. This bit does not cause an interrupt request. Reset type: SYSRSn 0h (R/W) = Transmitter buffer or shift register or both are loaded with data 1h (R/W) = Transmitter buffer and shift registers are both empty
5-2	RESERVED	R	0h	Reserved
1	RXBKINTENA	R/W	0h	Receiver-buffer/break interrupt enable. This bit controls the interrupt request caused by either the RXRDY flag or the BRKDT flag (bits SCIRXST.6 and .5) being set. However, RX/BK INT ENA does not prevent the setting of these flags. Reset type: SYSRSn 0h (R/W) = Disable RXRDY/BRKDT interrupt 1h (R/W) = Enable RXRDY/BRKDT interrupt

Table 36-12. SCICTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TXINTENA	R/W	0h	SCITXBUF-register interrupt enable. This bit controls the interrupt request caused by the setting of TXRDY flag bit (SCICTL2.7). However, it does not prevent the TXRDY flag from being set (which indicates SCITXBUF is ready to receive another character). 0 Disable TXRDY interrupt 1 Enable TXRDY interrupt. In non-FIFO mode, a dummy (or a valid) data has to be written to SCITXBUF for the first transmit interrupt to occur. This is the case when you enable the transmit interrupt for the first time and also when you re-enable (disable and then enable) the transmit interrupt. If TXINTENA is enabled after writing the data to SCITXBUF, it will not generate an interrupt. Reset type: SYSRSn 0h (R/W) = Disable TXRDY interrupt 1h (R/W) = Enable TXRDY interrupt

36.14.2.6 SCIRXST Register (Offset = 5h) [reset = 0h]

SCIRXST is shown in Figure 36-16 and described in Table 36-13.

Return to the Summary Table.

SCIRXST contains seven bits that are receiver status flags (two of which can generate interrupt requests). Each time a complete character is transferred to the receiver buffers (SCIRXEMU and SCIRXBUF), the status flags are updated.

Figure 36-16. SCIRXST Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RXERROR	RXRDY	BRKDT	FE	OE	PE	RXWAKE	RESERVED
R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h

Table 36-13. SCIRXST Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	RXERROR	R	0h	SCI receiver error flag. The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE). A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly it is cleared by an active SW RESET or by a system reset. Reset type: SYSRSn 0h (R/W) = No error flags set 1h (R/W) = Error flag(s) set
6	RXRDY	R	0h	SCI receiver-ready flag. When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, or by a system reset. Reset type: SYSRSn 0h (R/W) = No new character in SCIRXBUF 1h (R/W) = Character ready to be read from SCIRXBUF
5	BRKDT	R	0h	SCI break-detect flag. The SCI sets this bit when a break condition occurs. A break conditionoccurs when the SCI receiver data line (SCIRXD) remains continuously low for at least ten bits, beginning after a missing first stop bit. The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded. A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1. BRKDT is cleared by an active SW RESET or by a system reset. It is not cleared by receipt of a character after the break is detected. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit or by a system reset. Reset type: SYSRSn 0h (R/W) = No break condition 1h (R/W) = Break condition occurred

Table 36-13. SCIRXST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	FE	R	0h	SCI framing-error flag. The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit or by a system reset. Reset type: SYSRSn 0h (R/W) = No framing error detected 1h (R/W) = Framing error detected
3	OE	R	0h	SCI overrun-error flag. The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU or DMAC. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET or by a system reset. Reset type: SYSRSn 0h (R/W) = No overrun error detected 1h (R/W) = Overrun error detected
2	PE	R	0h	SCI parity-error flag. This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET or a system reset. Reset type: SYSRSn 0h (R/W) = No parity error or parity is disabled 1h (R/W) = Parity error is detected
1	RXWAKE	R	0h	Receiver wake-up-detect flag Reset type: SYSRSn 0h (R/W) = No detection of a receiver wake-up condition 1h (R/W) = A value of 1 in this bit indicates detection of a receiver wake-up condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following: - The transfer of the first byte after the address byte to SCIRXBUF (only in non-FIFO mode) - The reading of SCIRXBUF - An active SW RESET - A system reset
0	RESERVED	R	0h	Reserved

36.14.2.7 SCIRXEMU Register (Offset = 6h) [reset = 0h]

SCIRXEMU is shown in Figure 36-17 and described in Table 36-14.

Return to the Summary Table.

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented
it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

36.14.2.8 SCIRXBUF Register (Offset = 7h) [reset = 0h]

SCIRXBUF is shown in Figure 36-18 and described in Table 36-15.

Return to the Summary Table.

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RXBKINTENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

36.14.2.9 SCITXBUF Register (Offset = 9h) [reset = 0h]

SCITXBUF is shown in Figure 36-19 and described in Table 36-16.

Return to the Summary Table.

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

Bit	Field	Type	Reset	Description
15	ABD	R	0h	Auto-baud detect (ABD) bit Reset type: SYSRSn 0h (R/W) = Auto-baud detection is not complete. "A","a" character has not been received successfully. 1h (R/W) = Auto-baud hardware has detected "A" or "a" character on the SCI receive register. Auto-detect is complete.
14	ABDCLR	W	0h	ABD-clear bit Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on ABD flag bit. Bit reads back a zero. 1h (R/W) = Write 1 to clear ABD flag in bit 15.
13	CDC	R/W	0h	CDC calibrate A-detect bit Reset type: SYSRSn 0h (R/W) = Disables auto-baud alignment 1h (R/W) = Enables auto-baud alignment
12-8	RESERVED	R	0h	Reserved
7-0	FFTXDLY	R/W	0h	FIFO transfer delay. These bits define the delay between every transfer from FIFO transmit bufferto transmit shift register. The delay is defined in the number of SCI serial baud clock cycles. The 8 bit register could define a minimum delay of 0 baud clock cycles and a maximum of 256 baud clock cycles In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In FIFO mode, TXBUF should not be treated as one additional level of buffer. The delayed transmit feature will help to create an auto-flow scheme without RTS/CTS controls as in standard UARTS. When SCI is configured for one stop-bit, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to. When SCI is configured for two stop-bits, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to minus 1. Reset type: SYSRSn

36.14.2.13 SCIPRI Register (Offset = Fh) [reset = 0h]

SCIPRI is shown in Figure 36-23 and described in Table 36-20.

Return to the Summary Table.

SCIPRI determines what happens when an emulation suspend event occurs.

Serial Peripheral Interface (SPI)

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion via devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the master or slave operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

Topic **Page**

37.1 Introduction

37.1.1 Features

The SPI module features include:

- SPISOMI: SPI slave-output/master-input pin
- SPISIMO: SPI slave-input/master-output pin
- $\overline{\text{SPISTE}}$: SPI slave transmit-enable pin
- SPICLK: SPI serial-clock pin

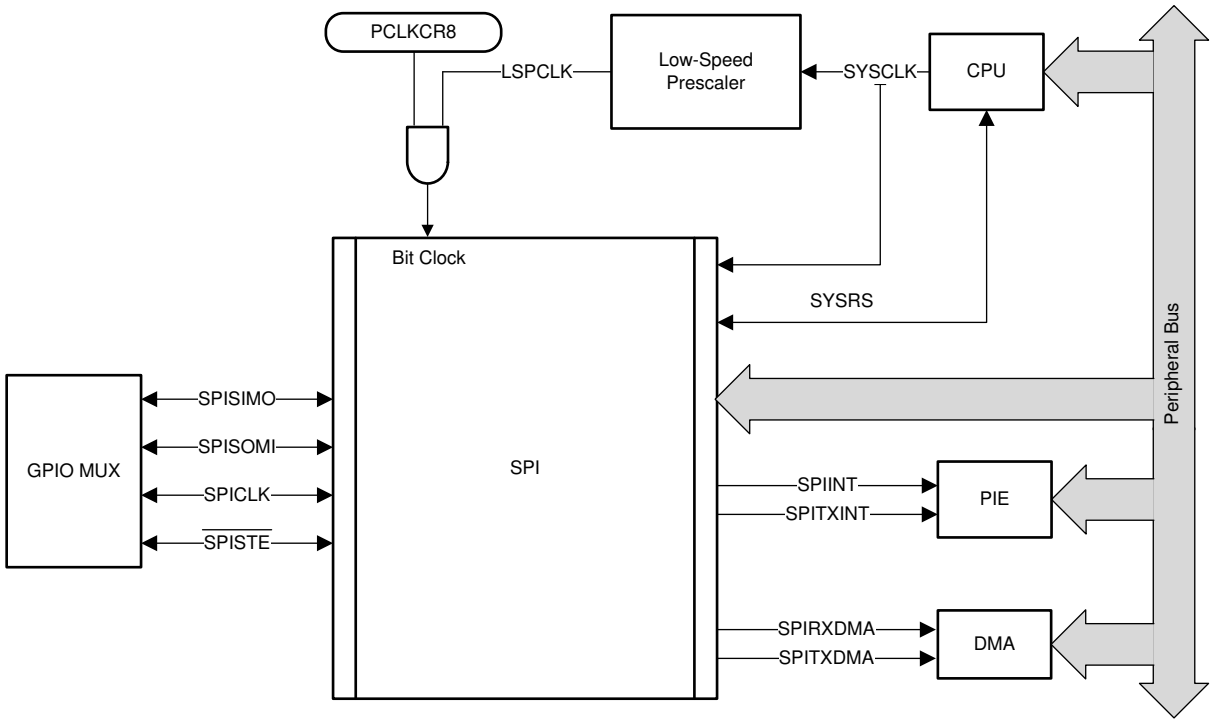
NOTE: All four pins can be used as GPIO if the SPI module is not used.

- Two operational modes: Master and Slave
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device-specific data manual for more details.
- Data word length: one to sixteen data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- 16-level transmit/receive FIFO
- DMA support
- High-speed mode
- Delayed transmit control
- 3-wire SPI mode
- $\overline{\text{SPISTE}}$ inversion for digital audio interface receive mode on devices with two SPI modules

37.1.2 Block Diagram

Figure 37-1 shows the SPI CPU interfaces.

Figure 37-1. SPI CPU Interface



37.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

37.2.1 SPI Module Signals

Table 37-1 classifies and provides a summary of the SPI module signals.

Table 37-1. SPI Module Signal Summary

Signal Name	Description
External Signals	
SPICLK	SPI clock
SPISIMO	SPI slave in, master out
SPISOMI	SPI slave out, master in
$\overline{\text{SPISTE}}$	SPI slave transmit enable
Control	
SPI Clock Rate	LSPCLK
Interrupt Signals	
SPIINT/SPIRXINT	Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT)
	Receive interrupt in FIFO mode
SPITXINT	Transmit interrupt in FIFO mode
DMA Triggers	
SPITXDMA	Transmit request to DMA
SPIRXDMA	Receive request to DMA

Special Considerations

The $\overline{\text{SPISTE}}$ signal provides the ability to gate any spurious clock and data pulses when the SPI is in slave mode. An active $\overline{\text{SPISTE}}$ will not allow the slave to receive data. This prevents the SPI slave from losing synchronization with the master. It is this reason that TI does not recommend that the $\overline{\text{SPISTE}}$ always be tied to the active state.

If the SPI slave does ever lose synchronization with the master, toggling SPISWRESET will reset internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI will interpret the next clock transition as the first bit of a new transmission. The register bit fields which are reset by SPISWRESET can be found in Section 37.5

Configuring a GPIO to emulate $\overline{\text{SPISTE}}$

In many systems, a SPI master may be connected to multiple SPI slaves using multiple instances of $\overline{\text{SPISTE}}$. Though this SPI module does not natively support multiple $\overline{\text{SPISTE}}$ signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the master. Rather than using the GPIO Mux to select $\overline{\text{SPISTE}}$, the application would configure pins to be GPIO outputs, one GPIO per SPI slave. Before transmitting any data, the application would drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select would be driven to the inactive state. This process can be repeated for many slaves which share the SPICLK, SPISIMO, and SPISOMI lines.

37.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification should be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *GPIO* chapter for more details on GPIO mux and settings.

37.2.2.1 GPIOs Required for High-Speed Mode

The high-speed mode of the SPI is available on the specified GPIO mux options in the device datasheet. To enable the high-speed enhancements, set SPICCR.HS_MODE to 1. Ensure that the capacitive loading on the pin does not exceed the value stated in the device Data Manual.

When not operating in high-speed mode, or if the capacitive loading on the pins exceed the value stated in the device Data Manual, SPICCR.HS_MODE should be set to 0.

37.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module.

The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT_FLAG), or there is overrun in the receiver (OVERRUN_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT_FLAG will generate an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN_FLAG will generate an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) will be set. SPIRXINT will be triggered in the PIE block if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

SPITXINT

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) will be set. SPITXINT will be triggered in the PIE block if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 37-2 and Table 37-2 show how these control bits influence the SPI interrupt generation.

Figure 37-2. SPI Interrupt Flags and Enable Logic Generation

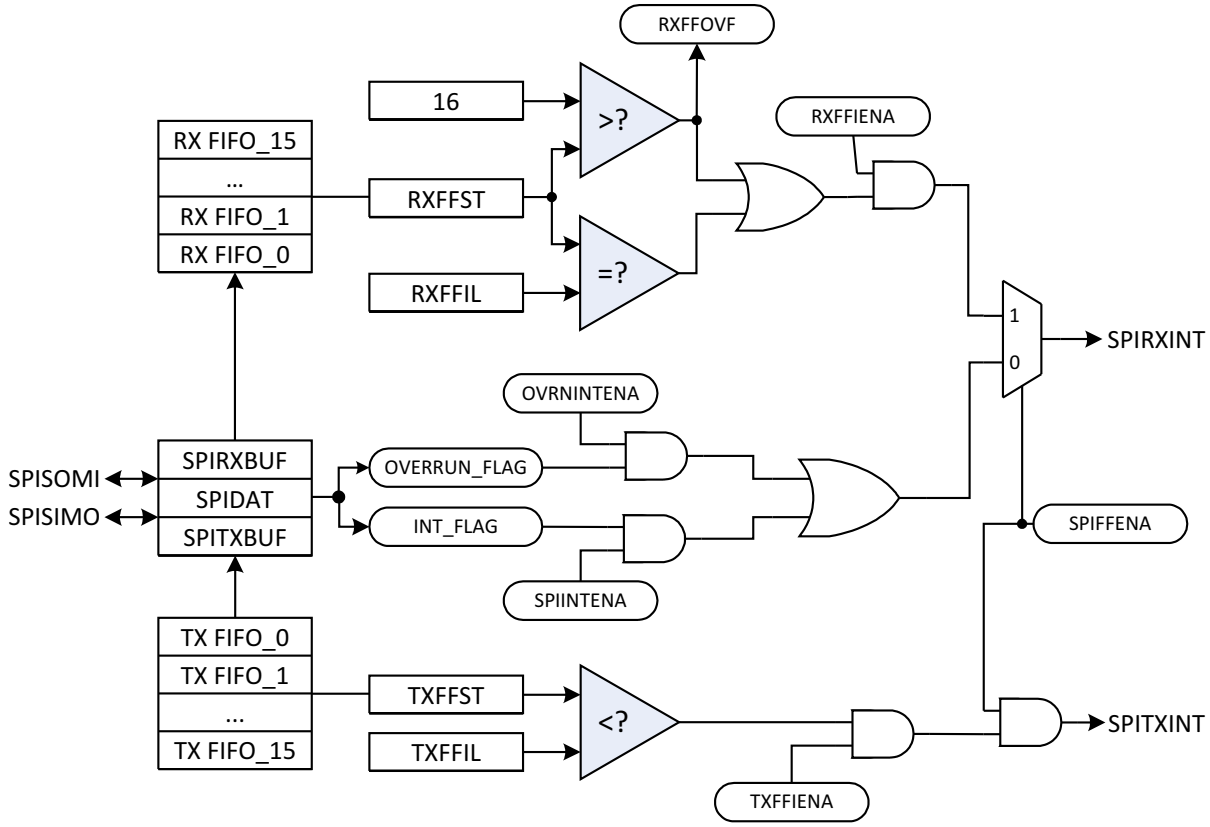


Table 37-2. SPI Interrupt Flag Modes

FIFO Options	SPI interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable (SPIFFENA)	Interrupt[1] Line
SPI without FIFO	Receive overrun	RXOVRN	OVRNINTENA	0	SPIRXINT
	Data receive	SPIINT	SPIINTENA	0	SPIRXINT
	Transmit empty	SPIINT	SPIINTENA	0	SPIRXINT
SPI FIFO mode	FIFO receive	RXFFIL	RXFFIENA	1	SPIRXINT
	Transmit empty	TXFFIL	TXFFIENA	1	SPITXINT

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in 28x devices.

37.2.4 DMA Support

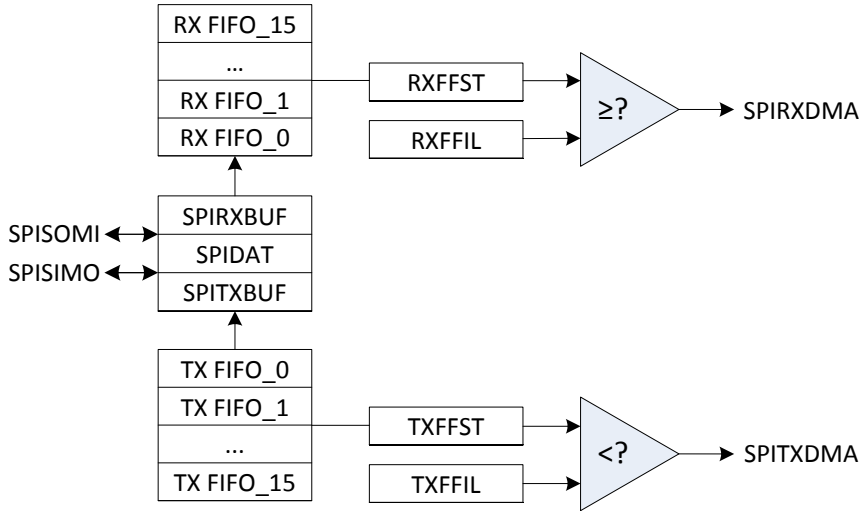
Both the CPU and DMA have access to the SPI data registers via the internal peripheral bus. This access is limited to 16-bit register read/writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled in order for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers refer to Section 37.3.8.

Figure 37-3 is a block diagram showing the DMA trigger generation from the SPI module.

Figure 37-3. SPI DMA Trigger Diagram



37.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

37.3.1 Introduction to Operation

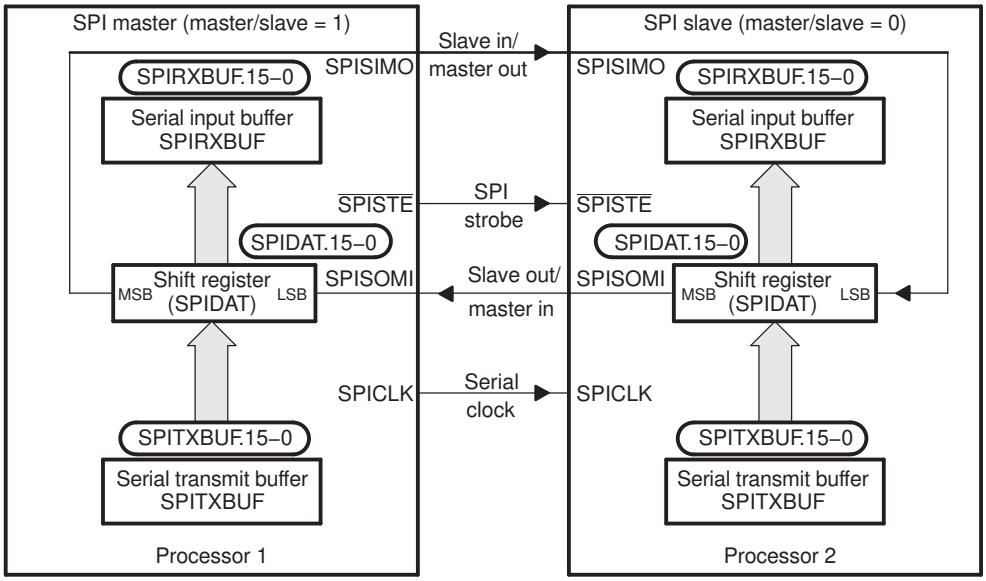
Figure 37-4 shows typical connections of the SPI for communications between two controllers: a master and a slave.

The master transfers data by sending the SPICLK signal. For both the slave and the master, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Master sends data; slave sends dummy data.
- Master sends data; slave sends data.
- Master sends dummy data; slave sends data.

The master can initiate data transfer at any time because it controls the SPICLK signal. The software, however, determines how the master detects when the slave is ready to broadcast data.

Figure 37-4. SPI Master/Slave Connection



The SPI can operate in master or slave mode. The MASTER_SLAVE bit selects the operating mode and the source of the SPICLK signal.

37.3.2 Master Mode

In master mode (MASTER_SLAVE = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPISIMO pin and latched from the SPISOMI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPISIMO pin, MSB (most significant bit) first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB (least significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

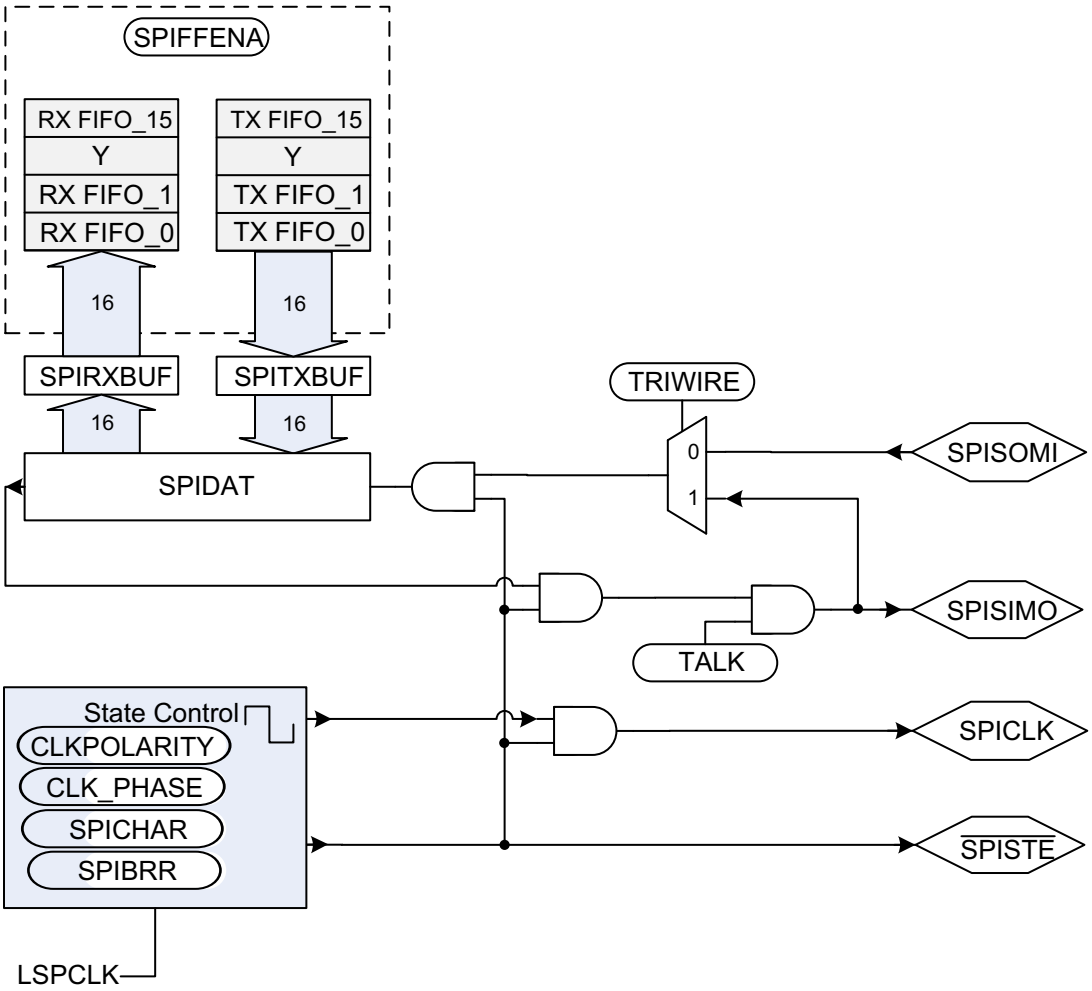
When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the Transmit Buffer Full Flag (BUFFULL_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the $\overline{\text{SPISTE}}$ pin serves as a chip-enable pin for a slave SPI device. This pin is driven low by the master before transmitting data to the slave and is taken high after the transmission is complete.

Figure 37-5 is a block diagram of the SPI in master mode. It shows the basic control blocks available in SPI master mode.

Figure 37-5. SPI Module Master Configuration



37.3.3 Slave Mode

In slave mode (MASTER_SLAVE = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock. The SPICLK input frequency should be no greater than the LSPCLK frequency divided by 4.

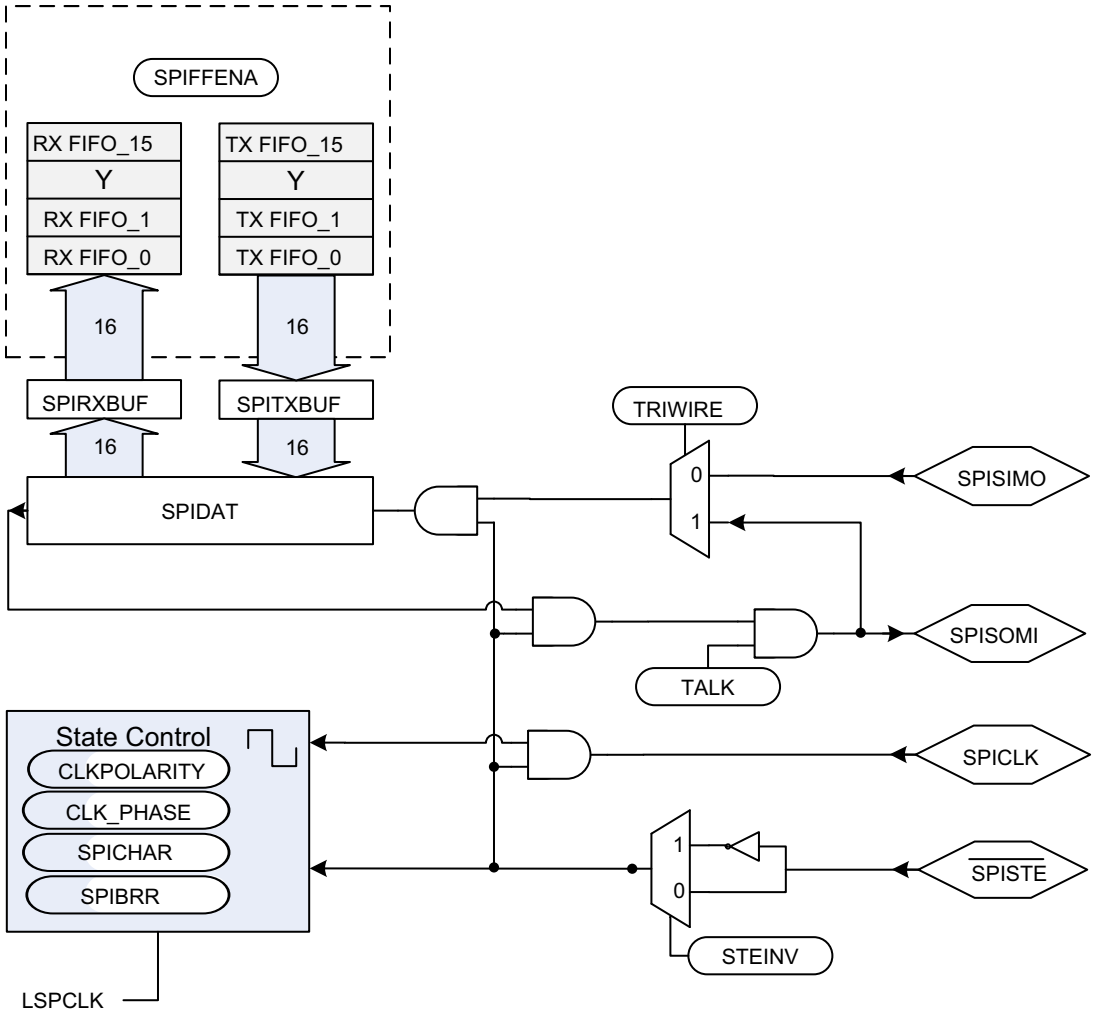
Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network master. Data written to the SPITXBUF register will be transferred to the SPIDAT register when all bits of the character to be transmitted have been shifted out of SPIDAT. If no character is currently being transmitted when SPITXBUF is written to, the data will be transferred immediately to SPIDAT. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts the data on the SPISIMO pin into SPIDAT. If data is to be transmitted by the slave simultaneously, and SPITXBUF has not been previously loaded, the data must be written to SPITXBUF or SPIDAT before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPISOMI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPISOMI is forced into the high-impedance state. This ensures that the SPI is still able to receive incoming data correctly. This TALK bit allows many slave devices to be tied together on the network, but only one slave at a time is allowed to drive the SPISOMI line.

The $\overline{\text{SPISTE}}$ pin operates as the slave-select pin. An active-low signal on the $\overline{\text{SPISTE}}$ pin allows the slave SPI to transfer data to the serial data line; an inactive- high signal causes the slave SPI serial shift register to stop and its serial output pin to be put into the high-impedance state. This allows many slave devices to be tied together on the network, although only one slave device is selected at a time.

Figure 37-6 is a block diagram of the SPI in slave mode. It shows the basic control blocks available in SPI slave mode.

Figure 37-6. SPI Module Slave Configuration



37.3.4 Data Format

The four-bit SPICHAR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from

previous transmission(s) that have been shifted to the left (shown in Example 37-1).

Example 37-1. Transmission of Bit From SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in bits SPICHAR)
2. The current value of SPIDAT = 737Bh

SPIDAT (before transmission)																
	0	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1
SPIDAT (after transmission)																
(TXed) 0 ←	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x[1] ← (RXed)
SPIRXBUF (after transmission)																
	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x[1]

(1) x = 1 if SPISOMI data is high; x = 0 if SPISOMI data is low; master mode is assumed.

37.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in slave or master mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the slave mode, the SPI clock is received on the SPICLK pin from the external source, and can be no greater than the LSPCLK frequency divided by 4.
- In the master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin, and can be no greater than the LSPCLK frequency divided by 4.

NOTE: The baud rate should be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device Data Manual for the maximum GPIO toggle frequency

Example 37-2 shows how to determine the SPI baud rates.

Example 37-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)} \quad (11)$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4} \quad (12)$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the master SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (which is device-specific) and the baud rate at which you will be operating.

The following example shows how to calculate the baud rate of the SPI module in standard SPI mode (HS_MODE=0).

Example 37-3. Baud Rate Calculation in Non-High Speed Mode (HS_MODE=0)

$$SPI\ Baud\ Rate = \frac{LSPCLK}{SPIBRR + 1'} \quad LSPCLK = 50\ MHz$$
$$= \frac{50 \times 10^6}{3 + 1}$$
$$= 12.5\ Mbps \tag{13}$$

37.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are as follows:

- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

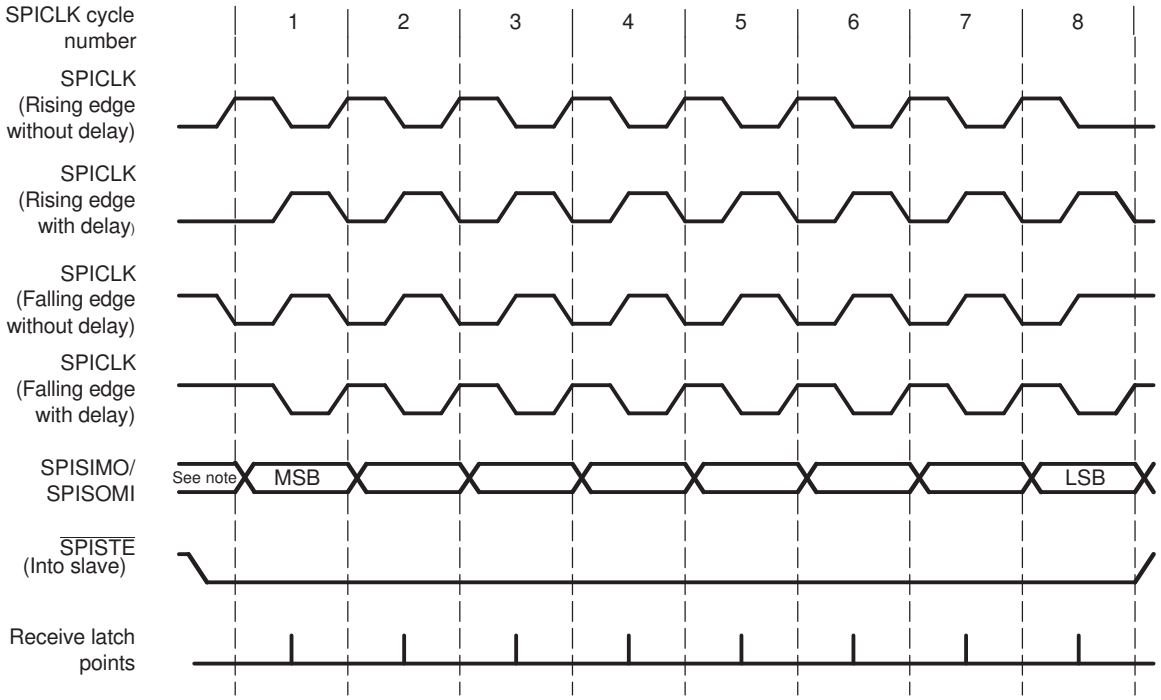
The selection procedure for the SPI clocking scheme is shown in Table 37-3. Examples of these four clocking schemes relative to transmitted and received data are shown in Figure 37-7.

Table 37-3. SPI Clocking Scheme Selection Guide

SPICLK Scheme	CLKPOLARITY	CLK_PHASE [1]
Rising edge without delay	0	0
Rising edge with delay	0	1
Falling edge without delay	1	0
Falling edge with delay	1	1

(1) The description of CLK_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.

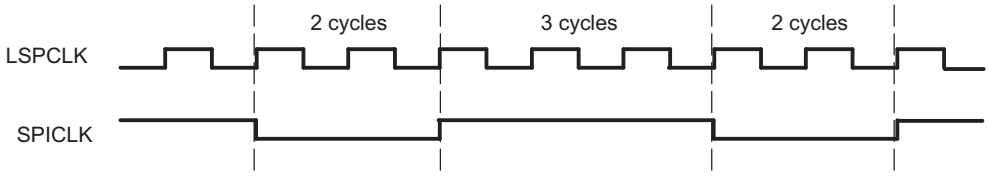
Figure 37-7. SPICLK Signal Options



Note: Previous data bit

SPICLK symmetry is retained only when the result of (SPIBRR+1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when CLKPOLARITY bit is clear (0). When CLKPOLARITY bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in Figure 37-8.

Figure 37-8. SPI: SPICLK-LSPCLK Characteristic When (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1



37.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode will work with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of its operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT will be active.
5. **Interrupts.** FIFO mode has two interrupts one for the transmit FIFO, SPITXINT and one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI will be disabled and this interrupt will service as SPI receive FIFO interrupt. For more information, refer to Section 37.2.3

6. **Buffers.** Transmit and receive buffers are each supplemented with a 16 word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer will be loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) will reset the FIFO pointers to zero when these bits are set to 1. The FIFOs will resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits will be 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

37.3.8 SPI DMA Transfers

37.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA_BURST_SIZE) should be no greater than 16 – TXFFIL in order to prevent the DMA from writing to an already full FIFO. This will lead to data loss and is not recommended.

For complete data transmission, please follow these steps:

1. Calculate the total number or words to be transmitted. [NUM_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM_WORDS: 128

TXFFIL: 8

DMA_TRANSFER_SIZE: (NUM_WORDS /TXFFIL) – 1 = (128/8) – 1 = 15 (16 transfers)

DMA_BURST_SIZE: (16 – TXFFIL) – 1 = (16 – 8) – 1 = 7 (8 words per burst)

NOTE: Avoid setting TXFFIL to 0h or 10h to ensure proper DMA configuration.

37.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST_SIZE) should be no greater than RXFFIL in order to prevent the DMA from reading from an empty FIFO. To ensure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size should equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, please follow these steps:

1. Calculate the number of words to be received. [NUM_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:
NUM_WORDS = 200
RXFFIL: 4
DMA_TRANSFER_SIZE: (NUM_WORDS /RXFFIL) – 1 = (200/4) – 1 = 49 (50 transfers)
DMA_BURST_SIZE = RXFFIL-1 = 3 (4 words per burst)

NOTE: Avoid setting RXFFIL to 0h to ensure proper DMA configuration.

37.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer the device Data Manual.

In order to achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single master to single slave configuration is supported.
- Loading on the pins must not exceed the value stated in the device Data Manual.

When configuring the GPIOs to support High-Speed mode, refer to Section 37.2.2.1 for more information.

37.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In master mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPISIMOx becomes the bi-directional SPIMOMIx (SPI master out, master in) pin, and SPISOMIx is no longer used by the SPI. In slave mode, if the TRIWIRE bit is set, SPISOMIx becomes the bi-directional SPISISOx (SPI slave in, slave out) pin, and SPISIMOx is no longer used by the SPI.

Table 37-4 indicates the pin function differences between 3-wire and 4-wire SPI mode for a master and slave SPI.

Table 37-4. 4-wire vs. 3-wire SPI Pin Functions

4-wire SPI	3-wire SPI (Master)	3-wire SPI(Slave)
SPICLKx	SPICLKx	SPICLKx
SPISTEx	SPISTEx	SPISTEx
SPISIMOx	SPIMOMIx	Free
SPISOMIx	Free	SPISISOx

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received by itself. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In master mode, in order to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPIMOMI pin) before reading from the data register.

Figure 37-9 and Figure 37-10 illustrate 3-wire master and slave mode.

Figure 37-9. SPI 3-wire Master Mode

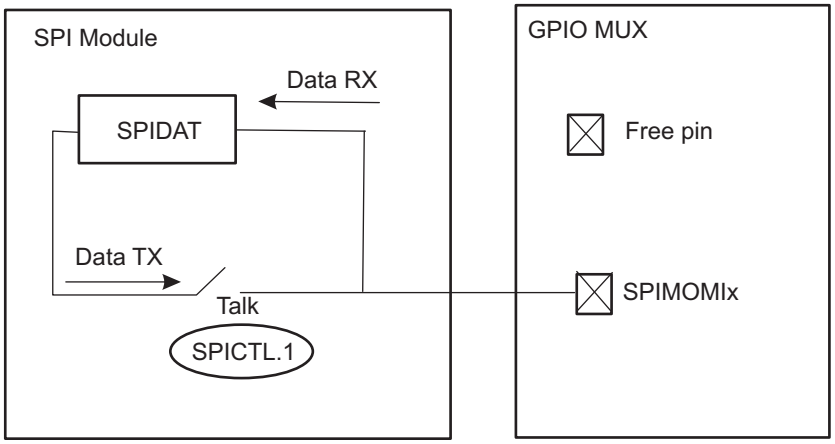


Figure 37-10. SPI 3-wire Slave Mode

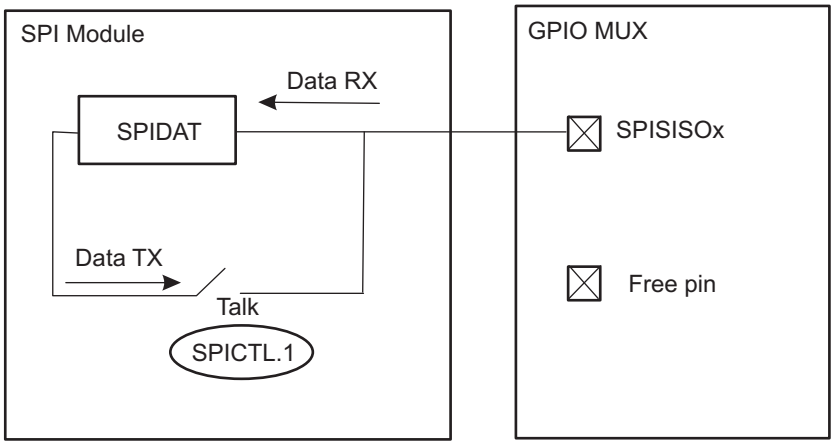

Table 37-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

Table 37-5. 3-Wire SPI Pin Configuration

Pin Mode	SPIPRI[TRIWIRE]	SPICTL[TALK]	SPISIMO	SPISOMI
		Master Mode		
4-wire	0	X	TX	RX
3-pin mode	1	0	RX	Disconnect from SPI
		1	TX/RX	
		Slave Mode		
4-wire	0	X	RX	TX
3-pin mode	1	0	Disconnect from SPI	RX
		1		TX/RX

37.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

37.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a slave module (MASTER_SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

37.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration may be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

To change the SPI configuration:

Step 1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.

Step 2. Configure the SPI as desired:

- Select either master or slave mode (MASTER_SLAVE).
- Choose SPICLK polarity and phase (CLKPOLARITY and CLK_PHASE).
- Set the desired baud rate (SPIBRR).
- Enable high speed mode if desired (HS_MODE).
- Set the SPI character length (SPICHAR).
- Clear the SPI Flags (OVERRUN_FLAG, INT_FLAG).
- Enable $\overline{\text{SPISTE}}$ inversion (STEINV) if needed.
- Enable 3-wire mode (TRIWIRE) if needed.
- If using FIFO enhancements:
  - Enable the FIFO enhancements (SPIFFENA).
  - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
  - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
  - Release SPI FIFO channels from reset (SPIRST).

Step 3. If interrupts are used:

- In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
- In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).

Step 4. Set SPISWRESET to 1 to release the SPI from the reset state.

NOTE: Do not change the SPI configuration when communication is in progress.

37.4.3 Configuring the SPI for High-Speed Mode

In order to achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100 MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO_CTRL_REGS.

During the SPI configuration procedure:

Set HS_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3. SPICLK = LSPCLK/(SPIBRR+1) = 25MHz

```
SpiaRegs.SPIBRR = 0x3;
```

There are no other differences in the configuration from normal SPI operation. Sending and receiving data, interrupts, and DMA operation will operate without change.

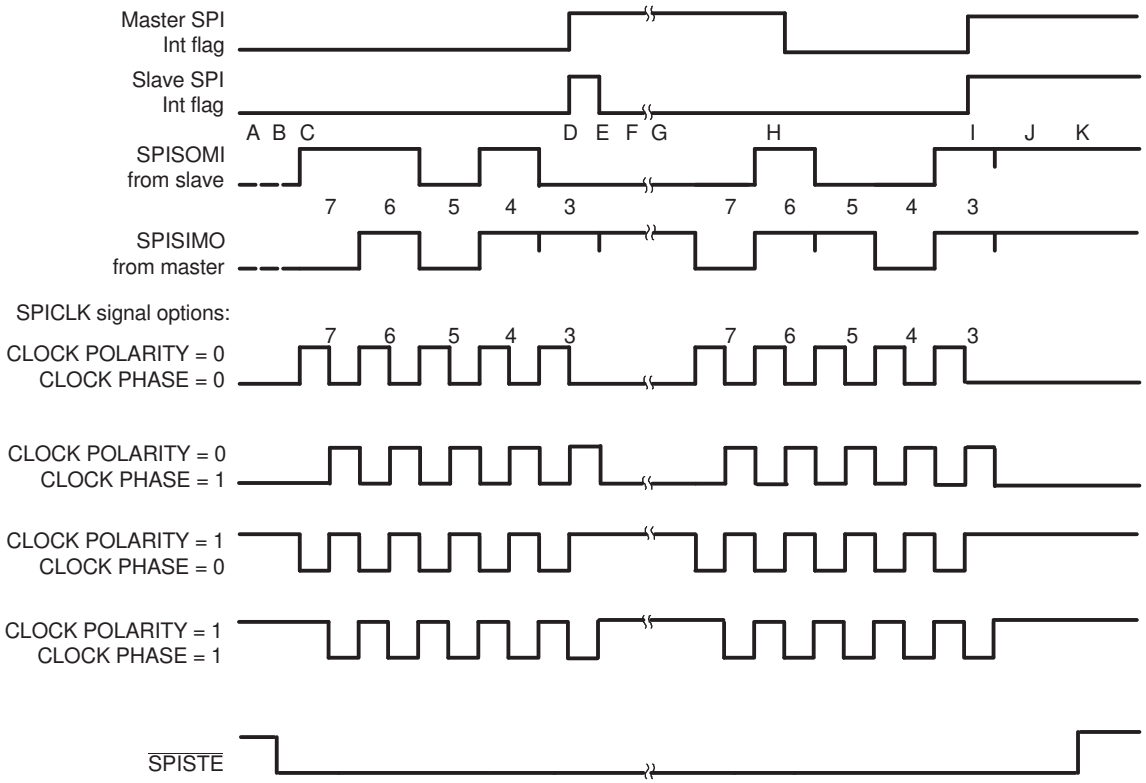
37.4.4 Data Transfer Example

The timing diagram shown in Figure 37-11 illustrates an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 37-8) shares similar characterizations with Figure 37-11 except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 37-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.

Figure 37-11. Five Bits per Character



A Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.

B Master sets the slave $\overline{\text{SPISTE}}$ signal low (active).

C Master writes 058h to SPIDAT, which starts the transmission procedure.

D First byte is finished and sets the interrupt flags.

E Slave reads 0Bh from its SPIRXBUF (right-justified).

F Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.

G Master writes 06Ch to SPIDAT, which starts the transmission procedure.

H Master reads 01Ah from the SPIRXBUF (right−justified).

I Second byte is finished and sets the interrupt flags.

J Master reads 89h and the slave reads 8Dh from their respective SPIRXBUF. After the user's software masks off the unused bits, the master receives 09h and the slave receives 0Dh.

K Master clears the slave $\overline{\text{SPISTE}}$ signal high (inactive).

37.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire master and slave mode. The following examples demonstrate these considerations.

In 3-wire master mode, SPICLKx, SPISTEx, and SPISIMOx pins must be configured as SPI pins (SPISOMIx pin can be configured as non-SPI pin). When the master transmits, it receives the data it transmits (because SPISIMOx and SPISOMIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

Example 37-4. 3-Wire Master Mode Transmit

```
Uint16 data;
Uint16 dummy;
```

Example 37-4. 3-Wire Master Mode Transmit (continued)

```
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data; // Master transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data from itself
                                                // bc it rx'd same data tx'd
```

To receive data in 3-wire master mode, the master must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data in order to initiate the transfer from the slave. Because the TALK bit is 0, unlike in transmit mode, the master dummy data does not appear on the SPISIMOx pin, and the master does not receive its own dummy data. Instead, the data from the slave is received by the master.

Example 37-5. 3-Wire Master Mode Receive

```
Uint16 rdata;
Uint16 dummy;

     SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
     SpiaRegs.SPITXBUF = dummy;                 // Send dummy to start tx
     // NOTE: because TALK = 0, data does not tx onto SPISIMOA pin
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
     rdata = SpiaRegs.SPIRXBUF;                 // Master reads data
```

In 3-wire slave mode, SPICLKx, SPISTEx, and SPISOMIx pins must be configured as SPI pins (SPISIMOx pin can be configured as non-SPI pin). Like in master mode, when transmitting, the slave receives the data it transmits and must clear this junk data from its receive buffer.

Example 37-6. 3-Wire Slave Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data;                  // Slave transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data from itself
```

As in 3-wire master mode, the TALK bit must be cleared to 0. Otherwise, the slave receives data normally.

Example 37-7. - 3-Wire Slave Mode Receive

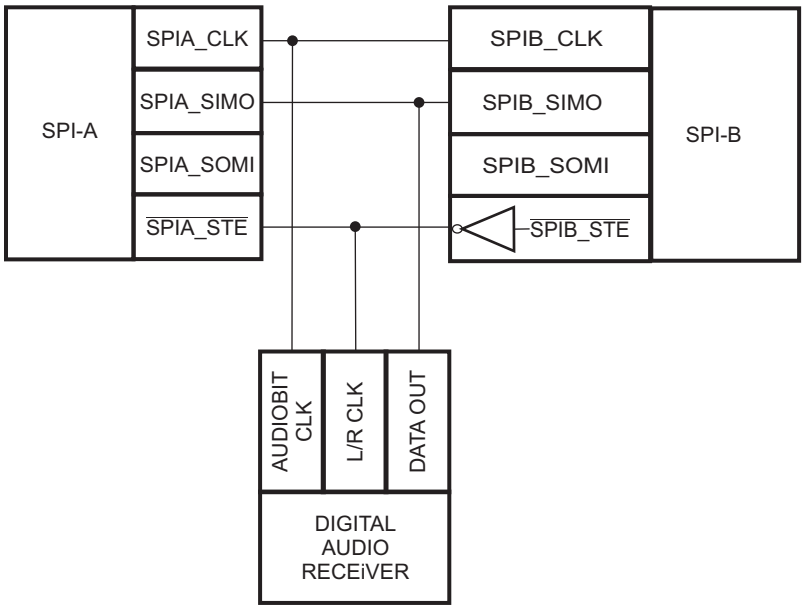
```
Uint16 rdata;
    SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    rdata = SpiaRegs.SPIRXBUF;                 // Slave reads data
```

37.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in slave mode. The SPI module that receives a normal active-low $\overline{\text{SPISTE}}$ signal stores right-channel data, and the SPI module that receives an inverted active-high $\overline{\text{SPISTE}}$ signal stores left-channel data from the master. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 37-12.

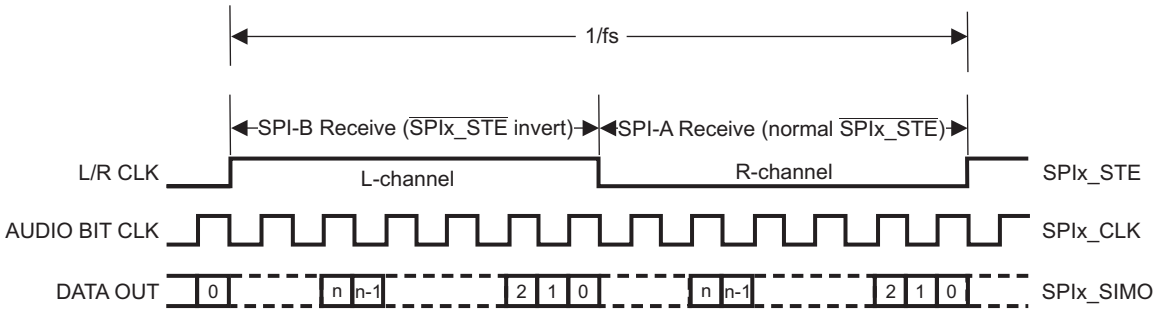
NOTE: This configuration is only applicable to slave mode (MASTER_SLAVE = 0). When the SPI is configured as master (MASTER_SLAVE = 1), the STEINV bit will have no effect on the $\overline{\text{SPISTE}}$ pin.

Figure 37-12. SPI Digital Audio Receiver Configuration Using Two SPIs



Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See your device-specific data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 37-13.

Figure 37-13. Standard Right-Justified Digital Audio Data Format



37.5 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

37.5.1 SPI Base Addresses

Table 37-6. SPI Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
SpiaRegs	SPI_REGS	SPIA_BASE	0x0000_6100	YES	YES	YES	YES	YES
SpibRegs	SPI_REGS	SPIB_BASE	0x0000_6110	YES	YES	YES	YES	YES
SpicRegs	SPI_REGS	SPIC_BASE	0x0000_6120	YES	YES	YES	YES	YES
SpidRegs	SPI_REGS	SPID_BASE	0x0000_6130	YES	YES	YES	YES	YES

37.5.2 SPI_REGS Registers

Table 37-7 lists the SPI_REGS registers. All register offset addresses not listed in Table 37-7 should be considered as reserved locations and the register contents should not be modified.

Table 37-7. SPI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SPICCR	SPI Configuration Control Register		Go
1h	SPICTL	SPI Operation Control Register		Go
2h	SPISTS	SPI Status Register		Go
4h	SPIBRR	SPI Baud Rate Register		Go
6h	SPIRXEMU	SPI Emulation Buffer Register		Go
7h	SPIRXBUF	SPI Serial Input Buffer Register		Go
8h	SPITXBUF	SPI Serial Output Buffer Register		Go
9h	SPIDAT	SPI Serial Data Register		Go
Ah	SPIFFTX	SPI FIFO Transmit Register		Go
Bh	SPIFFRX	SPI FIFO Receive Register		Go
Ch	SPIFFCT	SPI FIFO Control Register		Go
Fh	SPIPRI	SPI Priority Control Register		Go

Complex bit access types are encoded to fit into small table cells. Table 37-8 shows the codes that are used for access types in this section.

Table 37-8. SPI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

37.5.2.1 SPICCR Register (Offset = 0h) [reset = 0h]

SPICCR is shown in Figure 37-14 and described in Table 37-9.

Return to the Summary Table.

SPICCR controls the setup of the SPI for operation.

Figure 37-14. SPICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0

R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h			

Table 37-9. SPICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	SPISWRESET	R/W	0h	SPI Software Reset When changing configuration, you should clear this bit before the changes and set this bit before resuming operation. Reset type: SYSRSn 0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPISTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged. 1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set.
6	CLKPOLARITY	R/W	0h	Shift Clock Polarity This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin. Reset type: SYSRSn 0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. 1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.

Table 37-9. SPICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	HS_MODE	R/W	0h	High Speed Mode Enable Bits This bit determines if the High Speed mode is enabled. The correct GPIOs should be selected in the GPxGMUX/GPxMUX registers. Reset type: SYSRSn 0h (R/W) = SPI High Speed mode disabled. This is the default value after reset. 1h (R/W) = SPI High Speed mode enabled,
4	SPILBK	R/W	0h	SPI Loopback Mode Select Loopback mode allows module validation during device testing. This mode is valid only in master mode of the SPI. Reset type: SYSRSn 0h (R/W) = SPI loopback mode disabled. This is the default value after reset. 1h (R/W) = SPI loopback mode enabled, SIMO/SOMI lines are connected internally. Used for module self-tests.
3-0	SPICHAR	R/W	0h	Character Length Control Bits These four bits determine the number of bits to be shifted in or SPI CHAR0 out as a single character during one shift sequence. SPICHAR = Word length - 1 Reset type: SYSRSn 0h (R/W) = 1-bit word 1h (R/W) = 2-bit word 7h (R/W) = 8-bit word Fh (R/W) = 16-bit word

37.5.2.2 SPICTL Register (Offset = 1h) [reset = 0h]

SPICTL is shown in Figure 37-15 and described in Table 37-10.

Return to the Summary Table.

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (slave or master).

Figure 37-15. SPICTL Register

15	14	13	12	11	10	9	8

Table 37-10. SPICTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R	0h	Reserved
4	OVERRUNINTENA	R/W	0h	Overrun Interrupt Enable Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. Reset type: SYSRSn 0h (R/W) = Disable RECEIVER OVERRUN interrupts. 1h (R/W) = Enable RECEIVER_OVERRUN interrupts.
3	CLK_PHASE	R/W	0h	SPI Clock Phase Select This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (master or slave) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used. Reset type: SYSRSn 0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6). 1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit.
2	MASTER_SLAVE	R/W	0h	SPI Network Mode Control This bit determines whether the SPI is a network master or slave. SLAVE During reset initialization, the SPI is automatically configured as a network slave. Reset type: SYSRSn 0h (R/W) = SPI is configured as a slave. 1h (R/W) = SPI is configured as a master.

Table 37-10. SPICTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TALK	R/W	0h	Transmit Enable The TALK bit can disable data transmission (master or slave) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset. Reset type: SYSRSn 0h (R/W) = Disables transmission: - Slave mode operation: If not previously configured as a general-purpose I/O pin, the SPISOMI pin will be put in the high-impedance state. - Master mode operation: If not previously configured as a general-purpose I/O pin, the SPISIMO pin will be put in the high-impedance state. 1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPISTEn input pin.
0	SPIINTENA	R/W	0h	SPI Interrupt Enable This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit. Reset type: SYSRSn 0h (R/W) = Disables the interrupt. 1h (R/W) = Enables the interrupt.

37.5.2.3 SPISTS Register (Offset = 2h) [reset = 0h]

SPISTS is shown in Figure 37-16 and described in Table 37-11.

Return to the Summary Table.

SPISTS contrains interrupt and status bits.

Figure 37-16. SPISTS Register

15	14	13	12	11	10	9	8
RESERVED

Table 37-11. SPISTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	OVERRUN_FLAG	W1C	0h	SPI Receiver Overrun Flag This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways: - Writing a 1 to this bit - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited. Reset type: SYSRSn 0h (R/W) = A receive overrun condition has not occurred. 1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application). Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.

Table 37-11. SPISTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	INT_FLAG	RC	0h	SPI Interrupt Flag SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways: - Reading SPIRXBUF - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality. Reset type: SYSRSn 0h (R/W) = No full words have been received or transmitted. 1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.
5	BUFFULL_FLAG	R	0h	SPI Transmit Buffer Full Flag This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete. Reset type: SYSRSn 0h (R/W) = Transmit buffer is not full. 1h (R/W) = Transmit buffer is full.
4-0	RESERVED	R	0h	Reserved

37.5.2.4 SPIBRR Register (Offset = 4h) [reset = 0h]

SPIBRR is shown in Figure 37-17 and described in Table 37-12.

Return to the Summary Table.

SPIBRR contains the bits used for baud-rate selection.

Figure 37-17. SPIBRR Register

R-0h	R/W-0h						

Table 37-12. SPIBRR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	SPI_BIT_RATE	R/W	0h	SPI Baud Rate Control These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 master. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.) If the SPI is a network slave, the module receives a clock on the SPICLK pin from the network master. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the master should not exceed the slave SPI's LSPCLK signal divided by 4. In master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula: For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1) For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4 Reset type: SYSRSn 3h (R/W) = SPI Baud Rate = LSPCLK/4 4h (R/W) = SPI Baud Rate = LSPCLK/5 7Eh (R/W) = SPI Baud Rate = LSPCLK/127 7Fh (R/W) = SPI Baud Rate = LSPCLK/128

37.5.2.5 SPIRXEMU Register (Offset = 6h) [reset = 0h]

SPIRXEMU is shown in Figure 37-18 and described in Table 37-13.

Return to the Summary Table.

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

Figure 37-18. SPIRXEMU Register

ERXBn							
R-0h							

Table 37-13. SPIRXEMU Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	ERXBn	R	0h	Emulation Buffer Received Data SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set. This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately. It is recommended that you view SPIRXEMU in the normal emulator run mode. Reset type: SYSRSn

37.5.2.6 SPIRXBUF Register (Offset = 7h) [reset = 0h]

SPIRXBUF is shown in Figure 37-19 and described in Table 37-14.

Return to the Summary Table.

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

Figure 37-19. SPIRXBUF Register

Table 37-14. SPIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	RXBn	R	0h	Received Data Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register. Reset type: SYSRSn

37.5.2.7 SPITXBUF Register (Offset = 8h) [reset = 0h]

SPITXBUF is shown in Figure 37-20 and described in Table 37-15.

Return to the Summary Table.

SPITXBUF stores the next character to be tranmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no tranmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.

In master mode, if no tranmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

Table 37-15. SPITXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TXBn	R/W	0h	Transmit Data Buffer This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified. Reset type: SYSRSn

37.5.2.8 SPIDAT Register (Offset = 9h) [reset = 0h]

SPIDAT is shown in Figure 37-21 and described in Table 37-16.

Return to the Summary Table.

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

Figure 37-21. SPIDAT Register

Table 37-18. SPIFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RXFFOVF	R	0h	Receive FIFO Overflow Flag Reset type: SYSRSn 0h (R/W) = Receive FIFO has not overflowed. This is a read-only bit. 1h (R/W) = Receive FIFO has overflowed, read-only bit. More than 16 words have been received in to the FIFO, and the first received word is lost.
14	RXFFOVFCLR	W	0h	Receive FIFO Overflow Clear Reset type: SYSRSn 0h (R/W) = Write 0 does not affect RXFFOVF flag bit, Bit reads back a zero. 1h (R/W) = Write 1 to clear SPIFFRX[RXFFOVF].
13	RXFIFORESET	R/W	1h	Receive FIFO Reset Reset type: SYSRSn 0h (R/W) = Write 0 to reset the FIFO pointer to zero, and hold in reset. 1h (R/W) = Re-enable receive FIFO operation.
12-8	RXFFST	R	0h	Receive FIFO Status Reset type: SYSRSn 0h (R/W) = Receive FIFO is empty. 1h (R/W) = Receive FIFO has 1 word. 2h (R/W) = Receive FIFO has 2 words. 10h (R/W) = Receive FIFO has 16 words, which is the maximum. 1Fh (R/W) = Reserved.
7	RXFFINT	R	0h	Receive FIFO Interrupt Flag Reset type: SYSRSn 0h (R/W) = RXFIFO interrupt has not occurred. This is a read-only bit. 1h (R/W) = RXFIFO interrupt has occurred. This is a read-only bit.
6	RXFFINTCLR	W	0h	Receive FIFO Interrupt Clear Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on RXFIFINT flag bit, Bit reads back a zero. 1h (R/W) = Write 1 to clear SPIFFRX[RXFFINT] flag
5	RXFFIENA	R/W	0h	RX FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = RX FIFO interrupt based on RXFFIL match (greater than or equal to) will be disabled. 1h (R/W) = RX FIFO interrupt based on RXFFIL match (greater than or equal to) will be enabled.

Table 37-18. SPIFFRX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	RXFFIL	R/W	1Fh	Receive FIFO Interrupt Level Bits Receive FIFO generates an interrupt when the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The default value of these bits after reset is 11111. This avoids frequent interrupts after reset, as the receive FIFO will be empty most of the time. Reset type: SYSRSn 0h (R/W) = A RX FIFO interrupt request is generated when there is 0 or more words in the RX buffer. 1h (R/W) = A RX FIFO interrupt request is generated when there are 1 or more words in the RX buffer. 2h (R/W) = A RX FIFO interrupt request is generated when there are 2 or more words in the RX buffer. 10h (R/W) = A RX FIFO interrupt request is generated when there are 16 words in the RX buffer. 1Fh (R/W) = Reserved.

37.5.2.11 SPIFFCT Register (Offset = Ch) [reset = 0h]

SPIFFCT is shown in Figure 37-24 and described in Table 37-19.

Return to the Summary Table.

SPIFFCT controls the FIFO transmit delay bits.

Table 37-19. SPIFFCT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	TXDLY	R/W	0h	FIFO Transmit Delay Bits These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer. Reset type: SYSRSn 0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word. 1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word. 2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word. FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.

37.5.2.12 SPIPRI Register (Offset = Fh) [reset = 0h]

SPIPRI is shown in Figure 37-25 and described in Table 37-20.

Return to the Summary Table.

SPIPRI controls auxillary functions for the SPI including emulation control, SPISTE inversion, and 3-wire control.

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RESERVED	R/W	0h	Reserved
5	SOFT	R/W	0h	Emulation Soft Run This bit only has an effect when the FREE bit is 0. Reset type: SYSRSn 0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point. 1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used. Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty. In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.
4	FREE	R/W	0h	Emulation Free Run These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Emulation mode is selected by the SOFT bit 1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.
3-2	RESERVED	R	0h	Reserved

Table 37-20. SPIPRI Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	STEINV	R/W	0h	SPISTEn Inversion Bit On devices with 2 SPI modules, inverting the SPISTE signal on one of the modules allows the device to receive left and right- channel digital audio data. This bit is only applicable to slave mode. Writing to this bit while configured as master (MASTER_SLAVE = 1) has no effect Reset type: SYSRSn 0h (R/W) = SPISTEn is active low (normal) 1h (R/W) = SPISTE is active high (inverted)
0	TRIWIRE	R/W	0h	SPI 3-wire Mode Enable Reset type: SYSRSn 0h (R/W) = Normal 4-wire SPI mode. 1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In master mode, the SPISIMO pin becomes the SPIMOMI (master receive and transmit) pin and SPISOMI is free for non-SPI use. In slave mode, the SPISOMI pin becomes the SPISISO (slave receive and transmit) pin and SPISIMO is free for non-SPI use.

Universal Serial Bus (USB) Controller

This chapter discusses the features and functions of the universal serial bus (USB) controller.

Topic **Page**

38.1 Introduction

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. It has thirty-two endpoints, sixteen for IN transactions and sixteen for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

38.2 Features

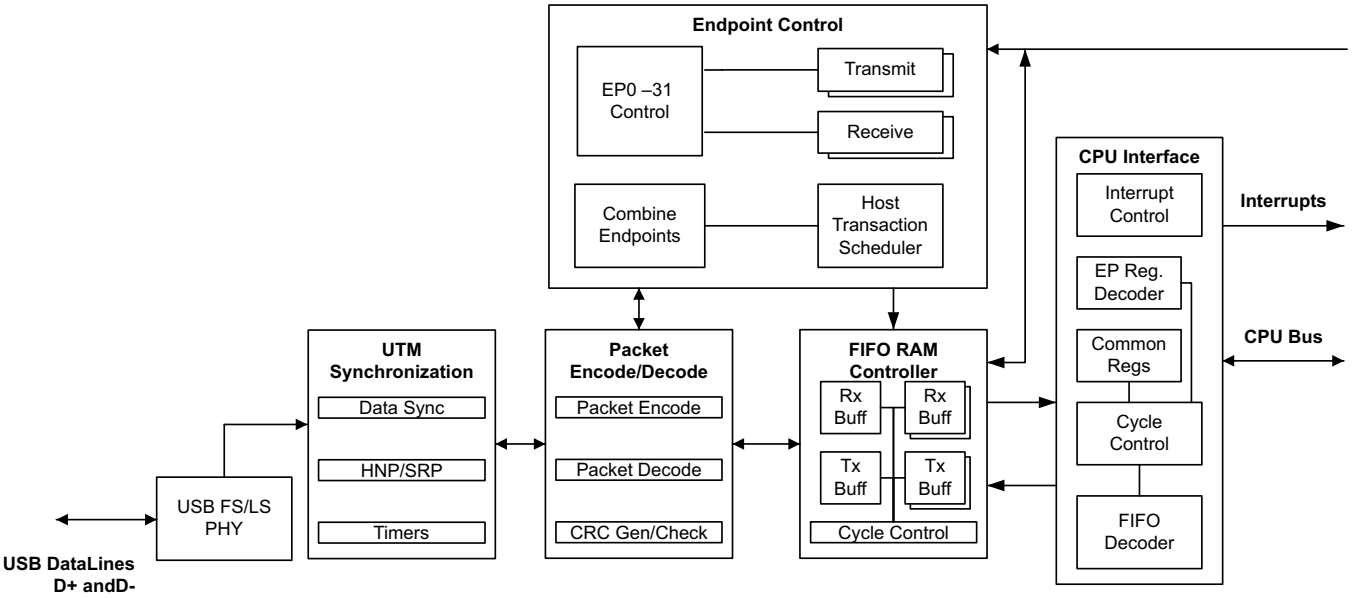
The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) operation in host and device modes as well as low-speed (1.5 Mbps) operation in host mode
- Integrated PHY
- Three transfer types: Control, Interrupt, and Bulk
- Thirty-two endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Fifteen configurable IN endpoints and fifteen configurable OUT endpoints
- Four KB dedicated endpoint memory

38.2.1 Block Diagram

The USB block diagram is shown in Figure 38-1.

Figure 38-1. USB Block Diagram



38.2.2 Signal Description

The USB controller requires a total of three signals (D+, D-, and V_{Bus}) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the pins D+ and D- have special buffers to support USB. As such, their position on the chip is not user-selectable. These pins at reset are, by default, GPIOs. They must be configured before being used as USB function pins. Bits 10 and 11 in the GPIO B Analog Mode Select register (GPBAMSEL) should be set to choose the USB function. The signals USB bus voltage (V_{BUS}), external power enable (EPEN), and power fault (PFLT) are not hardwired to any pin and some applications will require they be implemented in software via a GPIO. Software that implements these signals is available in the USB software library.

38.2.3 VBus Recommendations

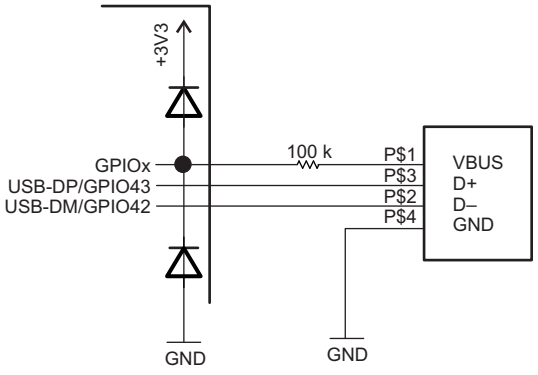
Most applications do not need to monitor V_{Bus}. Because of this, a dedicated V_{Bus} monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do NOT need to monitor V_{Bus}. If you are designing a self-powered device, you will need to actively monitor the state of the V_{Bus} pin in order to ensure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™ it is stated respectively that:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when V_{BUS} is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When V_{BUS} is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0 it is also stated that the D+/D- pull-up resistor should be applied within 100ms of V_{Bus} reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. In this chapter we will discuss the hardware part of the V_{Bus} monitoring solution. The corresponding software will be discussed briefly, but for examples and an explanation, please consult the USB software guide.

The pins of this microcontroller are not 5V tolerant, and because of this, the V_{Bus} signal cannot be directly connected to a GPIO pin. Directly connecting 5V to a pin of the microcontroller will destroy the I/O buffer of the pin and possibly more of the chip. The most cost-effective way of making any pin capable of reading a 5V input is to use a series resistance in conjunction with the ESD diode clamps already present inside the device on every pin. It is recommended to use a 100kΩ series resistor between the V_{Bus} signal and the pin chosen to monitor it. A diagram of this setup is shown in Figure 38-2.

Figure 38-2. USB Scheme



In the above diagram, if V_{Bus} is above or below 3.3V and 0V respectively, one of the ESD clamp diodes will be forward-biased, allowing current to flow through the 100KΩ resistor. The purpose of the diode clamps is to protect the pins of the microcontroller from very short overvoltage spikes of a high magnitude. They do this by clamping the voltage excursion to one of the supply rails. We are effectively requiring the ESD clamps to do the same thing they were designed to do, but instead of a short high magnitude pulse, we are giving them a long low magnitude static value via the 100kΩ resistor.

Any pin that has digital input/output functionality could potentially be used to monitor V_{Bus}, but the use of an interrupt-capable GPIO is recommended. A pin that does not have external interrupt capability may also be used, but the input state of the pin must be polled periodically by the application software to ensure appropriate action is taken whenever V_{Bus} is applied or removed. If an interrupt-capable GPIO is chosen, it should be configured to generate an interrupt on both the rising and falling edge. More information on external interrupts can be found in the *System Control and Interrupts* chapter. Example code that implements V_{Bus} monitoring using external interrupts and takes the appropriate actions is documented in the USB Software Guide and can be found in the associated USB software package.

38.3 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to V_{BUS} and configured to generate an interrupt when the V_{BUS} level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

NOTE: When USB is used in the system, the minimum system frequency is 30 MHz.

38.3.1 Operation as a Device

This section describes how the USB controller performs when it is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device should use the dedicated control endpoint on the USB controller’s endpoint 0.

38.3.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT) and thirty configurable endpoints (fifteen IN and fifteen OUT) that can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions. The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. They should be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

38.3.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the fifteen configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USBTXFIFOADD) register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USBTXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

Note: The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register should not be written to while data is in the FIFO as unexpected results may occur.

Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USBTXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USBTXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USBTXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USBTXCSRLn register at this point indicates how many packets may be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

Note: Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS) register. This bit is set by default, so it must be cleared to enable double-packet buffering.

38.3.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the fifteen configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USBRXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USBRXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

Note: In all cases, the maximum packet size must not exceed the FIFO size.

Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USBRXCSRL[*n*]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USBRXCSRH[*n*]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USBRXCSRL[*n*] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

Note: The FULL bit in USBRXCSRL[*n*] is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USBRXCSRH[*n*] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

Note: Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS) register. This bit is set by default, so it must be cleared to enable double-packet buffering.

38.3.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

38.3.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USBCSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what should have been the last packet.
3. The Host sends more than USBRXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USBCSRL0 register.

Setting the Device Address

When a Host is attempting to enumerate the USB device, it requests that the device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USBFADDR) register. However, care should be taken when writing to USBFADDR to avoid changing the address before the transaction is complete. This register should only be set after the SET_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USBFADDR register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

Note: If the USBFADDR register is set to the new value as soon as the device receives the OUT transaction with the SET_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

38.3.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state.

38.3.1.1.6 Start of Frame

When the USB controller is operating in device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USBFRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the USBFRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

38.3.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USBEPIDX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts

- Generates a RESET interrupt

38.3.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the USBPOWER register. When the SOFTCONN bit is set, the PHY is placed in its normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

Note: The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

38.3.2 Operation as a Host

When the USB controller is operating in Host mode, it can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions are supported. This section describes the USB controller's actions when it is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint’s receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints should take into account the maximum packet size for an endpoint.

- Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller should use the dedicated control endpoint to communicate with a device’s endpoint 0.

38.3.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with device(s) that are connected. The endpoints consist of a dedicated control IN endpoint, a dedicated control OUT endpoint, fifteen configurable OUT endpoints, and fifteen configurable IN endpoints.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller’s FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as fifteen independent OUT and fifteen independent IN transactions to any endpoints on any device. The IN and OUT controls are paired in fifteen sets of registers. However, they can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device’s bulk OUT endpoint 1, while the IN portion is communicating with a device’s interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications via a hub, the relevant USB Receive Functional Address Endpoint n (USBRXFUNCADDRn) or USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

38.3.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USBCSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USBCSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USBRXCSRHn register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USBRXCSRHn causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn) register associated with the endpoint should be configured to the number of packets to be transferred. The USB controller decrements the value in the USBRQPKTCOUNTn register following each request. When the USBRQPKTCOUNTn value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USBRQPKTCOUNTn should be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USBRXMAXPn register) such as may occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USBCSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USBCSRL0 register.

38.3.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USBTXCSRLn register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USBTXCSRHn register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USBTXCSRLn register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USBTXCSRLn register.

38.3.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every n frames, where n is the interval set via the USB Host Transmit Interval Endpoint n (USBTXINTERVAL[*n*]) or USB Host Receive Interval Endpoint n (USBRXINTERVAL[*n*]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

38.3.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller via a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint n (USBRXHUBADDRn) and USB Receive Hub Port Endpoint n (USBRXHUBPORTn) or the USB Transmit Hub Address Endpoint n (USBTXHUBADDRn) and USB Transmit Hub Port Endpoint n (USBTXHUBPORTn) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYPE0) (endpoint 0), USB Host Configure Transmit Type Endpoint n (USBTXTYPEn), or USB Host Configure Receive Type Endpoint n (USBRXTYPEn) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

38.3.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

38.3.2.7 Host SUSPEND

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20 ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

38.3.2.8 USB RESET

If the RESET bit in the USBPOWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to ensure correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts its frame counter and transaction scheduler.

38.3.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the USB device Control (USBDEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USBDEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

38.3.3 DMA Operation

The USB module's DMA trigger signals are not supported on this device. The DMA controller may be used to read and write the USB FIFOs via software triggering. see the Direct Memory Access (DMA) chapter for more details about programming the DMA controller.

38.3.4 Address/Data Bus Bridge

The USB controller on this device is the same controller that is on the Stellaris devices. This controller was originally designed to connect to an ARM AHB bus, but has been modified in order to function with the C28x device’s bus architecture. The modifications made are largely invisible to the user application, but there are some things to note.

- The USB memory space is 8 bits wide, while the C28x memory space is 16 bits wide.
- 32 and 16 bit accesses (r/w) are completely transparent to the user application code, no changes need be made.
- The C28x core only supports 8 bit accesses through a byte intrinsic type. This can be used to perform 8 bit reads or writes to the USB controller.
  - int &__byte(int *array, unsigned int byte_index);
  - *array = ptr to address to access, byte_index = always 0 (for USB)
    See Table 38-1 for example.
  - See the TMS320C28x Optimizing C/C++ Compiler User's Guide (SPRU514) and the TMS320C28x Assembly Language Tools User's Guide (SPRU513)
- Because of the bridge, the memory view of the USB controller memory space in CCS isn’t a 1:1 representation of what is in the controller
  - When the view mode is
    - 32 bit or 16 bit, even address are effectively duplicated, ignore odd addresses.
    - 8 bit, Even addresses from within the controller are duplicated into odd address in the view window; old addresses from within the controller are not displayed.
      See Table 38-2 for example.

38.4 Initialization and Configuration

To use the USB controller, the peripheral clock must be enabled via the System Control module's PCLKCR11 register. In addition, the USB PHY signals must be connected to their respective pins via the GPIO module's GPBAMSEL register. Set bits 10 and 11 for USB0DM (GPIO42) and USB0DP (GPIO43).

Set up the auxiliary PLL so a 60 MHz output clock is provided to the USB module. This fixed frequency is required for all USB operations. See the *System Control* chapter for more details.

In host mode, the USB controller is responsible for supplying power to the bus. To avoid incorrectly supplying voltage to the bus, the external power control signal, USB0EPEN, should be kept inactive on start-up. This can be done by connecting the USB0EPEN and USB0PFLT pins to the USB controller as soon as possible.

38.4.1 Pin Configuration

In order to give the user more flexibiliity, the signals External Power Enable (EPEN) and Power Fault (PFLT) were not implemented in hardware. Instead, it is left up to the user to implement these signals in software. Examples of how to implement these signals in software can be found in the F2806x USB Software Guide.

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to V_{BUS} must be disabled to allow the external host controller to supply power. Usually, the EPEN signal is used to control the external regulator and should be negated to avoid having two devices driving the V_{BUS} power pin on the USB connector.

When the USB controller is acting as a host, it is in control of two signals that are attached to an external voltage supply that provides power to V_{BUS}. The Host controller uses the EPEN signal to enable or disable power to the V_{BUS} pin on the USB connector. An input pin, PFLT, provides feedback when there has been a power fault on V_{BUS}. The PFLT signal can be configured to either automatically negate the EPEN signal to disable power, and/or it can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both EPEN and PFLT are fully configurable in the USB controller. The controller also provides interrupts on device insertion and removal to allow the Host controller code to respond to these external events.

38.4.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to V_{BUS} via the USB0EPEN signal.

38.5 USB Global Interrupts

Global interrupt enable, flag, and clear registers have been added to ensure that no interrupt is missed. The USB interrupt can be enabled or blocked using the INTEN bit. The INTFLG bit indicates whether an interrupt has occured or not. Finally the INTFLGCLR bit will clear the INTFLG when the value '1' is written to the field.

38.6 USB Registers

38.6.1 USB Base Address

Table 38-3. USB Base Address Table (C28)

DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
USB_BASE	0x0004_0000	YES	-	-	-	YES

(1) This register is used in Device mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode.

(2) This register is used in Host mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode. The USB controller is in Device mode upon reset, so the reset values shown for these registers apply to the Device mode definition.

38.6.3 USB Register Descriptions

This section describes the Universal Serial Bus registers.

38.6.3.1 USB Device Functional Address Register

(USBFADDR), offset 0x000

The USB function address 8-bit register (USBFADDR) contains the 7-bit address of the device part of the transaction.

When the USB controller is being used in device mode (the HOST bit in the USBDEVCTL register is clear), this register must be written with the address received through a SET_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

Mode(s): Device

For special considerations when writing this register, see the *Setting the Device Address* in Section 38.3.1.1.4.

USBFADDR is shown in Figure 38-3 and described in Table 38-6.

Figure 38-3. Function Address Register (USBFADDR)

7	6	0
Reserved	FUNCADDR	
R-0	R/W-0	

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 38-6. Function Address Register (USBFADDR) Field Descriptions

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	FUNCADDR	0-7Fh	Function Address of Device as received through SET_ADDRESS.

38.6.3.2 USB Power Management Register

(USBPOWER), offset 0x001

The power management 8-bit register (USBPOWER) is used for controlling SUSPEND and RESUME signaling, and some basic operational aspects of the USB controller.

Mode(s): Host Device

USBPOWER in Host Mode is shown in Figure 38-4 and described in Table 38-7.

Figure 38-4. Power Management Register (USBPOWER) in Host Mode

7	4	3	2	1	0
Reserved		RESET	RESUME	SUSPEND	PWRDNPHY
R-0		R/W-0	R/W-0	R/W-1S	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 38-7. Power Management Register (USBPOWER) in Host Mode Field Descriptions

Bit	Field	Value	Description
7-4	Reserved	0	Reserved
3	RESET		RESET signaling.
		0	Ends RESET signaling on the bus.
		1	Enables RESET signaling on the bus.
2	RESUME		RESUME signaling. The bit should be cleared by software 20 ms after being set.
		0	Ends RESUME signaling on the bus.
		1	Enables RESUME signaling when the Device is in SUSPEND mode.
1	SUSPEND		SUSPEND mode
		0	No effect
		1	Enables SUSPEND mode.
0	PWRDNPHY		Power Down PHY
		0	No effect
		1	Powers down the internal USB PHY.

USBPOWER in Device Mode is shown in Figure 38-5 and described in Table 38-8.

Figure 38-5. Power Management Register (USBPOWER) in Device Mode

7	6	5	4	3	2	1	0
Reserved	SOFTCONN	Reserved		RESET	RESUME	SUSPEND	PWRDNPHY
R/W-0	R/W-0	R-0		R/W-0	R/W-0	R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 38-8. Power Management Register (USBPOWER) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	Reserved		Reserved
6	SOFTCONN		Soft Connect/Disconnect
		0	The USB D+/D- lines are tri-stated.
		1	The USB D+/D- lines are enabled.
5-4	Reserved	0	Reserved
3	RESET		RESET signaling
		0	Ends RESET signaling on the bus.
		1	Enables RESET signaling on the bus.

Table 38-8. Power Management Register (USBPOWER) in Device Mode Field Descriptions (continued)

Bit	Field	Value	Description
2	RESUME		RESUME signaling. The bit should be cleared by software 10 ms (a maximum of 15 ms) after being set.
		0	Ends RESUME signaling on the bus.
		1	Enables RESUME signaling when the Device is in SUSPEND mode.
1	SUSPEND		SUSPEND mode.
		0	This bit is cleared when software reads the interrupt register or sets the RESUME bit above.
		1	The USB controller is in SUSPEND mode.
0	PWRDNPHY		Power Down PHY
		0	No effect
		1	Powers down the internal USB PHY.

38.6.3.3 USB Transmit Interrupt Status Register (USBTXIS), offset 0x002

NOTE: Use caution when reading this register. Performing a read may change bit status.

The USB transmit interrupt status 16-bit read-only register (USBTXIS) indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–15. The meaning of the EPn bits in this register is based on the mode of the device. The EP1 through EP15 bits always indicate that the USB controller is sending data; however, in Host mode, the bits refer to OUT endpoints; while in Device mode, the bits refer to IN endpoints. The EP0 bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt.

Mode(s): Host Device

USBTXIS is shown in Figure 38-6 and described in Table 38-9.

Figure 38-6. USB Transmit Interrupt Status Register (USBTXIS)

15	14	13	12	11	10	9	8
EP15	EP14	EP13	EP12	EP11	EP10	EP9	EP8
R-0							
7	6	5	4	3	2	1	0
EP7	EP6	EP5	EP4	EP3	EP2	EP1	EP0
R-0							

Table 38-9. USB Transmit Interrupt Status Register (USBTXIS) Field Descriptions

Bit	Field	Value	Description
15	EP15		TX Endpoint 15 Interrupt
		0	No interrupt
		1	The Endpoint 15 transmit interrupt is asserted.
14	EP14		TX Endpoint 14 Interrupt
		0	No interrupt
		1	The Endpoint 14 transmit interrupt is asserted.

38.6.3.4 USB Receive Interrupt Status Register (USBRXIS), offset 0x004

NOTE: Use caution when reading this register. Performing a read may change bit status.

The USB receive interrupt status 16-bit read-only register (USBRXIS) indicates which interrupts are currently active for receive endpoints 1–15.

Note: Bits relating to endpoints that have not been configured always return 0. All active interrupts are cleared when this register is read.

Mode(s): Host Device

USBRXIS is shown in Figure 38-7 and described in Table 38-10.

Figure 38-7. USB Transmit Interrupt Status Register (USBRXIS)

38.6.3.5 USB Transmit Interrupt Enable Register (USBTXIE), offset 0x006

The USB transmit interrupt enable 16-bit register (USBTXIE) provides interrupt enable bits for the interrupts in the USBTXIS register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the USBTXIS register is set. When a bit is cleared, the interrupt in the USBTXIS register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

Mode(s): Host Device

USBTXIS is shown in Figure 38-8 and described in Table 38-11.

Figure 38-8. USB Transmit Interrupt Status Enable Register (USBTXIE)

10-0	FRAME	0-7FFh	Last received frame number

38.6.3.10 USB Endpoint Index Register (USBEPIDX), offset 0x00E

Each endpoint buffer can be accessed by configuring a FIFO size and starting address. The endpoint index 16-bit register (USBEPIDX) is used with the USBTXFIFOSZ, USBRXFIFOSZ, USBTXFIFOADD, and USBRXFIFOADD registers.

Mode(s): Host Device

USBEPIDX is shown in Figure 38-15 and described in Table 38-18.

Figure 38-15. USB Endpoint Index Register (USBEPIDX)

7	4	3	0
Reserved		EPIDX	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 38-18. USB Endpoint Index Register (USBEPIDX) Field Descriptions

Bit	Field	Value	Description
7-4	Reserved	0	Reserved
3-0	EPIDX	0-4h	Endpoint Index. This bit field configures which endpoint is accessed when reading or writing to one of the USB controller's indexed registers. A value of 0x0 corresponds to Endpoint 0 and a value of 0xF corresponds to Endpoint 15.

38.6.3.11 USB Test Mode Register (USBTEST), offset 0x00F

The USB test mode 8-bit register (USBTEST) is primarily used to put the USB controller into one of the four test modes for operation described in the USB Specification 2.0 , in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

Note: Only one of these bits should be set at any time.

Mode(s): Host Device

USBTEST in Host Mode is shown in Figure 38-16 and described in Table 38-19.

Figure 38-16. USB Test Mode Register (USBTEST) in Host Mode

7	6	5	4	0
FORCEH	FIFOACC	FORCEFS	Reserved	
R/W-0	R/W1S-0	R/W-0	R-0	

LEGEND: R/W = Read/Write; W = Write only; -*n* = value after reset

Table 38-19. USB Test Mode Register (USBTEST) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	FORCEH		Force Host Mode. While in this mode, status of the bus connection may be read using the DEV bit of the USBDEVCTL register. The operating speed is determined from the FORCEFS bit.
		0	No effect
		1	Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.
6	FIFOACC		FIFO Access
		0	No effect
		1	Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO.
5	FORCEFS		Force Full-Speed Mode
		0	The USB controller operates at Low Speed.
		1	Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
4-0	Reserved	0	Reserved

USBTEST in Device Mode is shown in Figure 38-17 and described in Table 38-20.

		1	Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
4-0	Reserved	0	Reserved

38.6.3.12 USB FIFO Endpoint Registers

USBFIFO[0]-USBFIFO[15]

NOTE: Use caution when reading these registers. Performing a read may change bit status.

The USB FIFO endpoint *n* 32-bit registers (USBFIFO[*n*]) provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

Transfers to and from FIFOs can be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see *Single-Packet Buffering* in Section 38.3.1.1.2). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–3, the associated FIFO is completely flushed.

For the specific offset for each FIFO register see Table 38-5.

Mode(s): Host Device

USBFIFO0-15 are shown in Figure 38-18 and described in Table 38-21.

Figure 38-18. USB FIFO Endpoint *n* Register (USBFIFO[*n*])

31	0
EPDATA	
R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 38-21. USB FIFO Endpoint *n* Register (USBFIFO[*n*]) Field Descriptions

Bit	Field	Reset	Description
31-0	EPDATA	0x0000.0000	Endpoint Data. Writing to this register loads the data into the Transmit FIFO and reading unloads data from the Receive FIFO.

38.6.3.13 USB Device Control Register

(USBDEVCTL), offset 0x060

The USB device control 8-bit register (USBDEVCTL) is used for controlling and monitoring the USB V_{BUS} line. If the PHY is suspended, no PHY clock is received and the V_{BUS} is not sampled. In addition, in Host mode, USBDEVCTL provides the status information for the current operating mode (Host or Device) of the USB controller. If the USB controller is in Host mode, this register also indicates if a full- or low-speed Device has been connected.

Mode(s): Host Device

USBDEVCTL is shown in Figure 38-19 and described in Table 38-22.

Figure 38-19. USB Device Control Register (USBDEVCTL)

7	6	5	4	3	2	1	0
DEV	FSDEV	LSDEV	VBUS		HOSTMODE	HOSTREQ	SESSION
R-1	R-0	R-0	R-0		R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 38-22. USB Device Control Register (USBDEVCTL) Field Descriptions

Bit	Field	Value	Description
7	DEV		Device mode
		0	The USB controller is operating on the OTG A side of the cable.
		1	The USB controller is operating on the OTG B side of the cable.
			Only valid while a session is in progress.
6	FSDEV		Full-Speed Device Detected
		0	A full-speed Device has not been detected on the port.
		1	A full-speed Device has been detected on the port.
5	LSDEV		Low-Speed Device Detected
		0	A low-speed Device has not been detected on the port.
		1	A low-speed Device has been detected on the port.
4-3	VBUS	0-3h	These read-only bits encode the current VBus level as follows:
		0	Below Session End. VBUS is detected as under 0.5 V.
		1h	Above Session End, below AValid. VBUS is detected as above 0.5 V and under 1.5 V.
		2h	Above AValid, below VBusValid. VBUS is detected as above 1.5 V and below 4.75 V.
		3h	Above VBusValid. VBUS is detected as above 4.75 V.
2	HOSTMODE		This read-only bit is set when the USB controller is acting as a Host.
		0	The USB controller is acting as a Device.
		1	The USB controller is acting as a Host.
			Only valid while a session is in progress.
1	HOSTREQ		When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed.
		0	No effect
		1	Initiates the Host Negotiation when SUSPENDmode is entered.

Table 38-22. USB Device Control Register (USBDEVCTL) Field Descriptions (continued)

Bit	Field	Value	Description
0	SESSION		Session Start/End When operating as a Host:
		0	When cleared by software, this bit ends a session.
		1	When set by software, this bit starts a session.
			When operating as a Device:
		0	The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect.
		1	The USB controller has started a session. When set by software, the Session Request Protocol is initiated.
			Clearing this bit when the USB controller is not suspended results in undefined behavior.

38.6.3.14 USB Transmit Dynamic FIFO Sizing Register (USBTXFIFOSZ), offset 0x062

The USB transmit dynamic FIFO sizing 8-bit register (USBTXFIFOSZ) allows the selected TX endpoint FIFOs to be dynamically sized. USBEPIDX is used to configure each transmit endpoint's FIFO size.

Mode(s): Host Device

USBTXFIFOSZ is shown in Figure 38-20 and described in Table 38-23.

38.6.3.15 USB Receive Dynamic FIFO Sizing Register (USBRXFIFOSZ), offset 0x063

The USB receive dynamic FIFO sizing 8-bit register (USBRXFIFOSZ) allows the selected RX endpoint FIFOs to be dynamically sized.

Mode(s): Host Device

USBRXFIFOSZ is shown in Figure 38-21 and described in Table 38-24.

Figure 38-21. USB Receive Dynamic FIFO Sizing Register (USBRXFIFOSZ)

38.6.3.16 USB Transmit FIFO Start Address Register (USBTXFIFOADD), offset 0x064

The USB transmit FIFO start address 16-bit register (USBTXFIFOADD) controls the start address of the selected transmit endpoint FIFOs.

Mode(s): Host Device

USBTXFIFOADDR is shown in Figure 38-22 and described in Table 38-25.

Figure 38-22. USB Transmit FIFO Start Address Register (USBTXFIFOADDR])

38.6.3.18 USB Connect Timing Register

(USBCONTIM), offset 0x07A

The USB connect timing 8-bit configuration register (USBCONTIM) specifies connection and negotiation delays.

Mode(s): Host Device

USBCONTIM is shown in Figure 38-24 and described in Table 38-27.

Figure 38-24. USB Connect Timing Register (USBCONTIM)

Bit	Field	Value	Description
7-4	WTCON	5h	The connect wait field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 μs.
3-0	WTID	Ch	The wait ID field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms.

38.6.3.19 USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF), offset 0x07D

USB full-speed last transaction to end of frame timing 8-bit configuration register (USBFSEOF) specifies the minimum time gap allowed between the start of the last transaction and the EOF for full-speed transactions.

Mode(s): Host Device

USBFSEOF is shown in Figure 38-25 and described in Table 38-28.

Figure 38-25. USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF)

Bit	Field	Reset	Description
7-0	FSEOFG	77h	The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 µs.

38.6.3.20 USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF), offset 0x07E

The USB low-speed last transaction to end of frame timing 8-bit configuration register (USBLSEOF) specifies the minimum time gap that is to be allowed between the start of the last transaction and the EOF for low-speed transactions.

Mode(s): Host Device

USBLSEOF is shown in Figure 38-26 and described in Table 38-29.

Figure 38-26. USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF)

Bit	Field	Reset	Description
7-0	LSEOFG	72h	The low-speed end-of-frame gap field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 µs. The default corresponds to 121.6 µs.

38.6.3.21 USB Transmit Functional Address Endpoint Registers

USBTXFUNCADDR[0] - USBTXFUNCADDR[15]

The transmit functional address endpoint *n* 8-bit registers (USBTXFUNCADDR[*n*]) record the address of the target function to be accessed through the associated endpoint (EP*n*). USBTXFUNCADDRx must be defined for each transmit endpoint that is used.

Note: USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBTXFUNCADDR[*n*] registers are shown in Figure 38-27 and described in Table 38-30.

Figure 38-27. USB Transmit Functional Address Endpoint *n* Registers (USBTXFUNCADDR[*n*])

7	Reserved	0	Reserved
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

38.6.3.22 USB Transmit Hub Address Endpoint Registers

USBTXHUBADDR[0] - USBTXHUBADDR[15]

The transmit hub address endpoint *n* 8-bit read/write registers (USBTXHUBADDR[*n*]), like USBTXHUBPORT[*n*], must be written only when a USB device is connected to transmit endpoint EP*n* via a USB 2.0 hub. This register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBTXHUBADDR[*n*] registers are shown in Figure 38-27 and described in Table 38-30.

Figure 38-28. USB Transmit Hub Address Endpoint *n* Registers (USBTXHUBADDR[*n*])

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

38.6.3.23 USB Transmit Hub Port Endpoint Registers

USBTXHUBPORT[0] - USBTXHUBPORT[15]

The transmit hub port endpoint *n* 8-bit read/write registers (USBTXHUBPORT[*n*]), like USBTXHUBADDR[*n*], must be written only when a full- or low-speed Device is connected to transmit endpoint EP*n* via a USB 2.0 hub. This register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBPORT0 is used for both receive and transmit for endpoint 0.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBTXHUBPORT*n* registers are shown in Figure 38-29 and described in Table 38-32.

Figure 38-29. USB Transmit Hub Port Endpoint *n* Registers (USBTXHUBPORT[*n*])

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	PORT	0	Hub Port specifies the USB hub port number.

38.6.3.24 USB Receive Functional Address Endpoint Registers

USBRXFUNCADDR[1] - USBRXFUNCADDR[15]

The recieve functional address endpoint *n* 8-bit read/write registers (USBRXFUNCADDR[*n*]) record the address of the target function to be accessed through the associated endpoint (EP*n*). USBRXFUNCADDRx must be defined for each receive endpoint that is used.

Note: USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBRXFUNCADDR[*n*] registers are shown in Figure 38-30 and described in Table 38-33.

Figure 38-30. USB Receive Functional Address Endpoint *n* Registers (USBFIFO[*n*])

7	6	0

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

38.6.3.25 USB Receive Hub Address Endpoint Registers

USBRXHUBADDR[1] - USBRXHUBADDR[15]

The receive hub address endpoint *n* 8-bit read/write registers (USBRXHUBADDR[*n*]), like [*n*], must be written only when a full- or low-speed Device is connected to receive endpoint EP*n* via a USB 2.0 hub. Each register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBRXHUBADDR[*n*] registers are shown in Figure 38-31 and described in Table 38-34.

Figure 38-31. USB Receive Hub Address Endpoint *n* Registers (USBRXHUBADDR[*n*])

Bit	Field	Value	Description
7	MULTTRAN		Multiple Translators
		0	Clear to indicate that the hub has a single transaction translator.
		1	Set to indicate that the hub has multiple transaction translators.
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

38.6.3.26 USB Receive Hub Port Endpoint Registers

USBRXHUBPORT[1] - USBRXHUBPORT[15]

The receive hub port endpoint *n* 8-bit read/write registers (USBRXHUBPORT[*n*]), like USBRXHUBADDR[*n*], must be written only when a full- or low-speed device is connected to receive endpoint EP*n* via a USB 2.0 hub. Each register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBPORT0 is used for both receive and transmit for endpoint 0.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBRXHUBPORT*n* registers are shown in Figure 38-32 and described in Table 38-35.

Figure 38-32. USB Transmit Hub Port Endpoint *n* Registers (USBRXHUBPORT[*n*])

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	PORT	0	Hub Port specifies the USB hub port number.

38.6.3.27 USB Maximum Transmit Data Endpoint Registers

USBTXMAXP[1] - USBTXMAXP[15]

The USB maximum transmit data endpoint *n* 16-bit registers (USBTXMAXP[*n*]) define the maximum amount of data that can be transferred through the selected transmit endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk and interrupt transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the FLUSH bit in USBTXCSRLn) after writing the new value to this register.

Note: USBTXMAXP[*n*] must be set to an even number of bytes for proper interrupt generation in DMA Basic Mode.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBTXMAXP[*n*] registers are shown in Figure 38-33 and described in Table 38-36.

Figure 38-33. USB Maximum Transmit Data Endpoint *n* Registers (USBTXMAXP[*n*])

Bit	Field	Value	Description
15-11	Reserved	0	Reserved
10-0	MAXLOAD		Maximum Payload specifies the maximum payload in bytes per transaction.

38.6.3.28 USB Control and Status Endpoint 0 Low Register (USBCSRL0), offset 0x102

The USB control and status endpoint 0 low 8-bit register (USBCSRL0) provides control and status bits for endpoint 0.

Mode(s): Host Device

USBCSRL0 in Host mode is shown in Figure 38-34 and described in Table 38-37.

Figure 38-34. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode

7	6	5	4	3	2	1	0
NAKTO	STATUS	REQPKT	ERROR	SETUP	STALLED	TXRDY	RXRDY
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 38-37. USB Control and Status Endpoint 0 Low Register(USBCSRL0) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	NAKTO		NAK Timeout. Software must clear this bit to allow the endpoint to continue.
		0	No timeout
		1	Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register.
6	STATUS		Status Packet. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction.
		0	No transaction
		1	Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set.
			This bit is automatically cleared when the STATUS stage is over.
5	REQPKT		Request Packet. This bit is cleared when the RXRDY bit is set.
		0	No request
		1	Requests an IN transaction.
4	ERROR		Error. Software must clear this bit.
		0	No error
		1	Three attempts have been made to perform a transaction with no response from the peripheral. The EP0 bit in the USBTXIS register is also set in this situation.
3	SETUP		Setup Packet. Setting this bit always clears the DT bit in the USBCSRH0 register to send a DATA0 packet.
		0	Sends an OUT token.
		1	Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
2	STALLED		Endpoint Stalled. Software must clear this bit.
		0	No handshake has been received.
		1	A STALL handshake has been received.
1	TXRDY		Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent.
		0	No transmit packet is ready.
		1	Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.
0	RXRDY		Receive Packet Ready. Software must clear this bit after the packet has been read from the FIFO to acknowledge that the data has been read from the FIFO.
		0	No receive packet has been received.
		1	Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

USBCSRL0 in Device mode is shown in Figure 38-35 and described in Table 38-38.

Figure 38-35. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode

7	6	5	4	3	2	1	0
SETENDC	RXRDYC	STALL	SETEND	DATAEND	STALLED	TXRDY	RXRDY

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 38-38. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	SETENDC		Setup End Clear
		0	No effect
		1	Writing a 1 to this bit clears the SETEND bit.
6	RXRDYC		RXRDY Clear
		0	No effect
		1	Writing a 1 to this bit clears the RXRDY bit.
5	STALL		Send Stall
		0	No effect
		1	Terminates the current transaction and transmits the STALL handshake.
			This bit is cleared automatically after the STALL handshake is transmitted.
4	SETEND		Setup end.
		0	A control transaction has not ended or ended after the DATAEND bit was set.
		1	A control transaction has ended before the DATAEND bit has been set. The EP0 bit in the USBTXIS register is also set in this situation.
			This bit is cleared by writing a 1 to the SETENDC bit.
3	DATAEND		Data end
		0	No effect
		1	Set this bit in the following situations: • When setting TXRDY for the last data packet • When clearing RXRDY after unloading the last data packet • When setting TXRDY for a zero-length data packet
			This bit is cleared automatically.
2	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has not been transmitted.
		1	A STALL handshake has been transmitted.
1	TXRDY		Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent.
		0	No transmit packet is ready.
		1	Software sets this bit after loading an IN data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.
0	RXRDY		Receive Packet Ready
		0	No receive packet has been received.
		1	A data packet has been received. The EP0 bit in the USBTXIS register is also set in this situation.
			This bit is cleared by writing a 1 to the RXRDYC bit.

38.6.3.29 USB Control and Status Endpoint 0 High Register (USBCSRH0), offset 0x103

The USB control and status endpoint 0 high 8-bit register (USBCSRH0) provides control and status bits for endpoint 0.

Mode(s): Host Device

USBCSRH0 in Host mode is shown in Figure 38-36 and described in Table 38-39.

Figure 38-36. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Host Mode

Table 38-39. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Host Mode Field Descriptions

Bit	Field	Value	Description
7-3	Reserved	0	Reserved
2	DTWE		Data Toggle Write Enable. This bit is automatically cleared once the new value is written.
		0	The DT bit cannot be written.
		1	Enables the current state of the endpoint 0 data toggle to be written (see DT bit).
1	DT		Data Toggle. When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is set, this bit may be written with the required setting of the data toggle. If DTWE is Low, this bit cannot be written. Care should be taken when writing to this bit as it should only be changed to RESET USB endpoint 0.
0	FLUSH		Flush FIFO. This bit is automatically cleared after the flush is performed.
		0	No effect
		1	Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared. **Note:** This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

USBCSRH0 in Device mode is shown in Figure 38-37 and described in Table 38-40.

Bit	Field	Value	Description
7-1	Reserved	0	Reserved
0	FLUSH		Flush FIFO. This bit is automatically cleared after the flush is performed.
		0	No effect
		1	Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared. **Note:** This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

38.6.3.30 USB Receive Byte Count Endpoint 0 Register

(USBCOUNT0), offset 0x108

The USB receive byte count endpoint 0 8-bit read-only register (USBCOUNT0) indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXRDY bit is set.

Mode(s): Host Device

USBCOUNT0 is shown in Figure 38-38 and described in Table 38-30.

Figure 38-38. USB Receive Byte Count Endpoint 0 Register (USBCOUNT0)

7	6	0
Reserved	COUNT	
R-0	R/W-0

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	COUNT	0	FIFO Count. COUNT is a read-only value that indicates the number of received data bytes in the endpoint 0 FIFO.

38.6.3.31 USB Type Endpoint 0 Register

(USBTYPE0), offset 0x10A

The USB type endpoint 0 8-bit register (USBTYPE0) must be written with the operating speed of the targeted Device being communicated with using endpoint 0.

Mode(s): Host

USBTYPE0 is shown in Figure 38-39 and described in Table 38-42.

Figure 38-39. USB Type Endpoint 0 Register (USBTYPE0)

7	6	5	0

7-6	SPEED	0	Operating Speed specifies the operating speed of the target Device. If selected, the target is assumed to have the same connection speed as the USB controller.
		0-1h	Reserved
		2h	Full
		3h	Low
5-0	Reserved	0	Reserved

38.6.3.32 USB NAK Limit Register

(USBNAKLMT), offset 0x10B

The USB NAK limit 8-bit read-only register (USBNAKLMT) sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their USBTXINTERVAL[*n*] and USBRXINTERVAL[*n*] registers.)

The number of frames selected is 2(m-1) (where m is the value set in the register, with valid values of 2–16). If the Host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

Note: A value of 0 or 1 disables the NAK timeout function.

Mode(s): Host

USBNAKLMT is shown in Figure 38-40 and described in Table 38-43.

Figure 38-40. USB NAK Limit Register (USBNAKLMT)

38.6.3.33 USB Transmit Control and Status Endpoint Low Register

USBTXCSRL[1] - USBTXCSRL[15]

The USB transmit control and status endpoint *n* low 8-bit registers (USBTXCSRL[*n*]) provide control and status bits for transfers through the currently selected transmit endpoint.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBTXCSRL[*n*] registers in Host Mode are shown in Figure 38-41 and described in Table 38-44.

Figure 38-41. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	SETUP	FLUSH	ERROR	FIFONE	TXRDY

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 38-44. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	NAKTO		NAK Timeout. Software must clear this bit to allow the endpoint to continue.
		0	No timeout
		1	Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[*n*] register.
6	CLRDT		Clear DataToggle
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBTXCSRH[*n*] register.
5	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has not been received
		1	Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	SETUP		Setup Packet.
		0	No SETUP token is sent.
		1	Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
			Note: Setting this bit also clears the DT bit in the USBTXCSRH[*n*] register.
3	FLUSH		Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO.
		0	No effect
		1	Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation.
			Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	ERROR		Error. Software must clear this bit.
		0	No error
		1	Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed in this situation.
			Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE		FIFO Not Empty
		0	The FIFO is empty
		1	At least one packet is in the transmit FIFO.

Table 38-44. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	TXRDY		Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EP*n* bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO.
		0	No transmit packet is ready.
		1	Software sets this bit after loading a data packet into the TX FIFO.

The USBTXCSRL[*n*] registers in Device Mode are shown in Table 38-44 and described in Figure 38-42.

Bit	Field	Value	Description
7	Reserved	0	Reserved
6	CLRDT		Clear Data Toggle
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBTXCSRH[*n*] register.
5	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has not been transmitted.
		1	A STALL handshake has been transmitted. The FIFO is flushed and the TXRDY bit is cleared.
4	STALL		Send Stall. Software clears this bit to terminate the STALL condition.
		0	No effect
		1	Issues a STALL handshake to an IN token.
3	FLUSH		Flush FIFO. This bit may be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. **Note:** This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
		0	No effect
		1	Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. This bit is cleared automatically.
2	UNDRN		Underrun. Software must clear this bit.
		0	No underrun
		1	An IN token has been received when TXRDY is not set.
1	FIFONE		FIFO Not Empty
		0	The FIFO is empty.
		1	At least one packet is in the transmit FIFO.

Table 38-45. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Device Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	TXRDY		Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO.
		0	No transmit packet is ready.
		1	Software sets this bit after loading a data packet into the TX FIFO. This bit is cleared by writing a 1 to the RXRDYC bit.

38.6.3.34 USB Transmit Control and Status Endpoint High Register

USBTXCSRH[1] - USBTXCSRH[15]

The USB transmit control and status endpoint *n* high 8-bit registers (USBTXCSRH[*n*]) provide additional control for transfers through the currently selected transmit endpoint.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBTXCSRH[*n*] registers in Host Mode are shown in Figure 38-43 and described in Table 38-46.

Figure 38-43. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 38-46. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	AUTOSET		Auto Set
		0	The TXRDY bit must be set manually.
		1	Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[*n*]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	Reserved	0	Reserved. Any writes to these bit(s) must always have a value of 0.
5	MODE		Mode **Note:** This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions.
		0	Enables the endpoint direction as RX.
		1	Enables the endpoint direction as TX.
4	DMAEN		DMA Request Enable **Note:** Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the transmit endpoint.
		1	Enables the DMA request for the transmit endpoint.
3	FDT		Force Data Toggle
		0	No effect
		1	Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. **Note:** This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD		DMA Request Mode **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete. **Note:** This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	DTWE		Data Toggle Write Enable. This bit is automatically cleared once the new value is written.
		0	The DT bit cannot be written.
		1	Enables the current state of the transmit endpoint data to be written (see DT bit).

Table 38-46. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	DT		Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint.

The USBTXCSRH[*n*] registers in Device Mode are shown in Figure 38-44 and described in Table 38-47.

		1	Enables the DMA request for the transmit endpoint.
3	FDT		Force Data Toggle
		0	No effect
		1	Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received.
2	DMAMOD		DMA Request Mode **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete.
0	Reserved	0	Reserved

38.6.3.35 USB Maximum Receive Data Endpoint Registers

USBRXMAXP[1] - USBRXMAXP[15]

The USB maximum receive data endpoint *n* 16-bit registers (USBRXMAXP[*n*]) define the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk and interrupt transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

Note: USBRXMAXP[*n*] must be set to an even number of bytes for proper interrupt generation in DMA Basic Mode.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBRXMAXP[*n*] registers are shown in Figure 38-45 and described in Table 38-48.

Figure 38-45. USB Maximum Receive Data Endpoint *n* Registers (USBRXMAXP[*n*])

15	11	10	0
Reserved		MAXLOAD	
R-0		R/W-000

Table 38-48. USB Maximum Receive Data Endpoint *n* Registers (USBTXMAXP[*n*]) Field Descriptions

Bit	Field	Value	Description
15-11	Reserved	0	Reserved
10-0	MAXLOAD	00	Maximum Payload specifies the maximum payload in bytes per transaction.

38.6.3.36 USB Receive Control and Status Endpoint Low Register

USBRXCSRL[1] - USBRXCSRL[15]

The USB receive control and status endpoint *n* low 8-bit register (USBCSRL[*n*]) provides control and status bits for transfers through the currently selected receive endpoint.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBCSRL[*n*] registers in Host mode are shown in Figure 38-46 and described in Table 38-49.

Figure 38-46. USB Receive Control and Status Endpoint *n* Low Register (USBCSRL[*n*]) in Host Mode

7	6	5	4	3	2	1	0

Table 38-49. USB Control and Status Endpoint n Low Register(USBCSRL[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	NAKTO		Clear Data Toggle.
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBRXCSRH[*n*] register.
6	STALLED		Endpoint Stalled. Software must clear this bit.
		0	No handshake has been received.
		1	A STALL handshake has been received. The EP*n* bit in the USBRXIS register is also set.
5	REQPKT		Request Packet. This bit is cleared when the RXRDY bit is set.
		0	No request
		1	Requests an IN transaction.
4	FLUSH		Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. **Note:**This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted.
		0	No effect
		1	Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared.
3	DATAERR / NAKTO		Data Error / NAK Timeout
		0	Normal operation
		1	Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[*n*] register. Software must clear this bit to allow the endpoint to continue.
2	ERROR		Error. Software must clear this bit. **Note:** This bit is only valid when the receive endpoint is operating in Bulk or Interrupt mode.
		0	No error
		1	Three attempts have been made to receive a packet and no data packet has been received. The EP*n* bit in the USBRXIS register is set in this situation.
1	FULL		FIFO Full
		0	The receive FIFO is not full.
		1	No more packets can be loaded into the receive FIFO.

Table 38-49. USB Control and Status Endpoint n Low Register(USBCSRL[*n*]) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	RXRDY		Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[*n*] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO.
		0	No data packet has been received.
		1	Indicates that a data packet has been received. The EP*n* bit in the USBTXIS register is also set in this situation.

USBCSRL0 in Device mode is shown in Figure 38-47 and described in Table 38-50.

Figure 38-47. USB Control and Status Endpoint *n* Low Register (USBCSRL[*n*]) in Device Mode

Table 38-50. USB Control and Status Endpoint 0 Low Register(USBCSRL[*n*]) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	CLRDT		Clear Data Toggle
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBRXCSRH[*n*] register.
6	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has been transmitted.
		1	A STALL handshake has been transmitted.
5	STALL		Send Stall. Software must clear this bit to terminate the STALL condition.
		0	No effect
		1	Issues a STALL handshake.
4	FLUSH		Flush FIFO. The CPU writes a 1 to this bit to flush the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO.
		0	No effect
		1	Flushes the next packet from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared. **Note:** This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted.
3	Reserved		Reserved
2	Reserved		Reserved
1	FULL		FIFO Full
		0	The receive FIFO is not full.
		1	No more packets can be loaded into the receive FIFO.
0	RXRDY		Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[*n*] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO.
		0	No data packet has been received.
		1	A data packet has been received. The EP*n* bit in the USBTXIS register is also set in this situation. This bit is cleared by writing a 1 to the RXRDYC bit.

38.6.3.37 USB Receive Control and Status Endpoint n High Register

USBRXCSRH[1] - USBRXCSRH[15]

The USB receive control and status endpoint *n* high 8-bit register (USBCSRL[*n*]) provides additional control and status bits for transfers through the currently selected receive endpoint.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBCSRH[*n*] registers in OTG A/Host mode are shown in Figure 38-48 and described in Table 38-51.

Figure 38-48. USB Receive Control and Status Endpoint *n* High Register (USBCSRH[*n*]) in Host Mode

7	6	5	4	3	2	1	0

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 38-51. USB Control and Status Endpoint n High Register (USBCSRH[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	AUTOCL		Auto Clear
		0	No effect
		1	Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[*n*] register, see Section 38.3.3.
6	AUTORQ		Auto Request **Note:** This bit is automatically cleared when a short packet is received.
		0	No effect
		1	Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared.
5	DMAEN		DMA Request Enable **Note:** Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the receive endpoint.
		1	Enables the DMA request for the receive endpoint.
4	Reserved		Reserved
3	DMAMOD		DMAMOD **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE		Data Toggle Write Enable. This bit is automatically cleared once the new value is written.
		0	The DT bit cannot be written.
		1	Enables the current state of the receive endpoint data to be written (see DT bit).
1	DT		Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint.
0	Reserved	0	Reserved

The USBCSRH[*n*] registers in Device mode are shown in Figure 38-49 and described in Table 38-52.

Table 38-52. USB Control and Status Endpoint 0 High Register(USBCSRH[*n*]) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	AUTOCL		Auto Clear
		0	No effect
		1	Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[*n*] register, see Section 38.3.3.
6	Reserved		Reserved
5	DMAEN		DMA Request Enable **Note:** Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the receive endpoint.
		1	Enables the DMA request for the receive endpoint.
4	DISNYET/PIDERR		Disable NYET / PID Error
		0	No effect
		1	For bulk or interrupt transactions: Disables the sending of NYET handshakes. When this bit is set, all successfully received packets are acknowledged, including at the point at which the FIFO becomes full.
3	DMAMOD		DMA Request Mode **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete.
0	Reserved	0	Reserved

38.6.3.38 USB Receive Byte Count Endpoint Registers

USBRXCOUNT[1] - USBRXCOUNT[15]

The USB receive byte count endpoint *n* 16-bit read-only registers hold the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

Note: The value returned changes as the FIFO is unloaded and is only valid while the RXRDY bit in the USBRXCSRLn register is set.

For the specific offset for each register see Table 38-5.

Mode(s): Host Device

The USBRXCOUNT[*n*] registers are shown in Figure 38-50 and described in Table 38-53.

Figure 38-50. USB Maximum Receive Data Endpoint *n* Registers (USBRXCOUNT[*n*])

15	13	12	0
Reserved		COUNT	
R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 38-53. USB Maximum Receive Data Endpoint *n* Registers (USBRXCOUNT[*n*]) Field Descriptions

Bit	Field	Value	Description
15-13	Reserved	0	Reserved
12-0	COUNT		Receive Packet Count indicates the number of bytes in the receive packet.

38.6.3.39 USB Host Transmit Configure Type Endpoint Register

USBTXTYPE[1] - USBTXTYPE[15]

The USB host transmit configure type endpoint *n* 8-bit registers (USBTXTYPE[*n*]) must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected transmit endpoint, and its operating speed.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBTXTYPE[*n*] registers are shown in Figure 38-51 and described in Table 38-54.

Figure 38-51. USB Host Transmit Configure Type Endpoint n Register (USBTXTYPE[*n*])

7	6	5	4	3	0

R/W-0		R/W-0		R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 38-54. USB Host Transmit Configure Type Endpoint n Register(USBTXTYPE[*n*]) Field Descriptions

Bit	Field	Value	Description
7-6	SPEED		Operating Speed. This bit field specifies the operating speed of the target Device:
		0h	Default. The target is assumed to be using the same connection speed as the USB controller.
		1h	Reserved
		2h	Full
		3h	Low
5-4	PROTO		Protocol. Software must configure this bit field to select the required protocol for the transmit endpoint:
		0h	Control
		1h	Reserved
		2h	Bulk
		3h	Interrupt
3-0	TEP	0	Target Endpoint Number. Software must configure this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during Device enumeration.

38.6.3.40 USB Host Transmit Interval Endpoint Register

USBTXINTERVAL[1] - USBTXINTERVAL[15]

The USB host transmit interval endpoint *n* 8-bit registers (USBTXINTERVAL[*n*]), for interrupt transfers, define the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The USBTXINTERVAL[*n*] registers values define a number of frames, as follows:

Table 38-55. USBTXINTERVAL[*n*] Frame Numbers

Transfer Type	Speed	Valid Values (m)	Interpretation
Interrupt	Low-speed or Full-speed	0x01-0xFF	The polling interval is *m* frames.
Bulk	Full-speed	0x02-0x10	The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBTXINTERVAL[*n*] registers are shown in Figure 38-51 and described in Table 38-54.

Figure 38-52. USB Host Transmit Interval Endpoint n Register (USBTXINTERVAL[*n*])

Bit	Field	Value	Description
7-0	TXPOLL / NAKLMT	0	TX Polling / NAK Limit The polling interval for interrupt transfers; the NAK limit for bulk transfers. See Table 38-55 for valid entries; other values are reserved.

38.6.3.41 USB Host Configure Receive Type Endpoint Register

USBRXTYPE[1] - USBRXTYPE[15]

The USB host configure receive type endpoint *n* 8-bit registers (USBRXTYPE[*n*]) must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected receive endpoint, and its operating speed.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBRXTYPE[*n*] registers are shown in Figure 38-53 and described in Table 38-57.

Figure 38-53. USB Host Configure Receive Type Endpoint n Register (USBRXTYPE[*n*])

		0h	Default. The target is assumed to be using the same connection speed as the USB controller.
		1h	Reserved
		2h	Full
		3h	Low
5-4	PROTO		Protocol. Software must configure this bit field to select the required protocol for the receive endpoint:
		0h	Control
		1h	Reserved
		2h	Bulk
		3h	Interrupt
3-0	TEP	0	Target Endpoint Number. Software must configure this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during Device enumeration.

38.6.3.42 USB Host Receive Polling Interval Endpoint Register

USBRXINTERVAL[1] - USBRXINTERVAL[15]

The USB host receive polling interval endpoint *n* 8-bit registers (USBRXINTERVAL[*n*]), for interrupt transfers, define the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The USBRXINTERVAL[*n*] registers values define a number of frames, as follows:

Table 38-58. USBRXINTERVAL[*n*] Frame Numbers

Transfer Type	Speed	Valid Values (m)	Interpretation
Interrupt	Low-speed or Full-speed	0x01-0xFF	The polling interval is *m* frames.
Bulk	Full-speed	0x02-0x10	The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBRXINTERVAL[*n*] registers are shown in Figure 38-51 and described in Table 38-54.

Figure 38-54. USB Host Receive Polling Interval Endpoint n Register (USBRXINTERVAL[*n*])

Table 38-59. USB Host Receive Polling Interval Endpoint n Register(USBRXINTERVAL[*n*]) Field Descriptions

Bit	Field	Value	Description
7-0	TXPOLL / NAKLMT	0	TX Polling / NAK Limit The polling interval for interrupt transfers, the NAK limit for bulk transfers. See Table 38-58 for valid entries; other values are reserved.

38.6.3.43 USB Request Packet Count in Block Transfer Endpoint Registers

USBRQPKTCOUNT[1] - USBRQPKTCOUNT[15]

The USB receive packet count in block transfer endpoint *n* 16-bit read/writer registers are used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint *n*. The USB controller uses the value recorded in this register to determine the number of requests to issue where the AUTORQ bit in the USBRXCSRH[*n*] register has been set. For more information about IN transactions as a host, see Section 38.3.2.2.

Note: Multiple packets combined into a single bulk packet within the FIFO count as one packet.

For the specific offset for each register see Table 38-5.

Mode(s): Host

The USBRQPKTCOUNT[*n*] registers are shown in Figure 38-55 and described in Table 38-60.

Figure 38-55. USB Request Packet Count in Block Transfer Endpoint *n* Registers (USBRQPKTCOUNT[*n*])

15	13	12	0
Reserved		COUNT	
R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 38-60. USB Request Packet Count in Block Transfer Endpoint *n* Registers (USBRQPKTCOUNT[*n*]) Field Descriptions

Bit	Field	Value	Description
15-13	Reserved	0	Reserved
12-0	COUNT		Block Transfer Packet Count sets the number of packets of the size defined by the MAXLOAD bit field that are to be transferred in a block transfer. **Note:** This is only used in Host mode when AUTORQ is set. The bit has no effect in Device mode or when AUTORQ is not set.

38.6.3.44 USB Receive Double Packet Buffer Disable Register

(USBRXDPKTBUFDIS), offset 0x340

The USB receive double packet buffer disable 16-bit register (USBTXIE) indicates which of the receive endpoints have disabled the double-packet buffer functionality (see *Double-Packet Buffering* in Section 38.3.1.1.1).

Mode(s): Host Device

USBRXDPKTBUFDIS is shown in Figure 38-56 and described in Table 38-61.

Figure 38-56. USB Receive Double Packet Buffer Disable Register (USBRXDPKTBUFDIS)

38.6.3.45 USB Transmit Double Packet Buffer Disable Register (USBTXDPKTBUFDIS), offset 0x342

The USB transmit double packet buffer disable 16-bit register (USBTXIE) indicates which of the transmit endpoints have disabled the double-packet buffer functionality (see *Double-Packet Buffering* in Section 38.3.1.1.1).

Mode(s): Host Device

USBTXDPKTBUFDIS is shown in Figure 38-57 and described in Table 38-62.

38.6.3.46 USB External Power Control Register (USBEPC), offset 0x400

The USB external power control 32-bit register (USBEPC) specifies the function of the two-pin external power interface (USB0EPEN and USB0PFLT). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary because the fault condition may require a response faster than one provided by firmware.

Mode(s): Host Device

USBEPC is shown in Figure 38-58 and described in Table 38-63.

Figure 38-58. USB External Power Control Register (USBEPC)

31							16
Reserved							
R-0

Table 38-63. USB External Power Control Register (USBEPC) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-8	PFLTACT		Power Fault Action. This bit field specifies how the USB0EPEN signal is changed when detecting a USB power fault.
		0h	Unchanged. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits.
		1h	Tristate. USB0EPEN is undriven (tristate).
		2h	Low. USB0EPEN is driven Low.
		3h	High. USB0EPEN is driven High.
7	Reserved	0	Reserved
6	PFLTAEN		Power Fault Action Enable. This bit specifies whether a USB power fault triggers any automatic corrective action regarding the driven state of the USB0EPEN signal.
		0	Disabled. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits.
		1	Enabled. The USB0EPEN output is automatically changed to the state specified by the PFLTACT field.
5	PFLTSEN		Power Fault Sense. This bit specifies the logical sense of the USB0PFLT input signal that indicates an error condition. The complementary state is the inactive state.
		0	Low Fault. If USB0PFLT is driven Low, the power fault is signaled internally (if enabled by the PFLTEN bit).
		1	High Fault. If USB0PFLT is driven High, the power fault is signaled internally (if enabled by the PFLTEN bit).
4	PFLTEN		Power Fault Input Enable. This bit specifies whether the USB0PFLT input signal is used in internal logic.
		0	Not Used. The USB0PFLT signal is ignored.
		1	Used. The USB0PFLT signal is used internally
3	Reserved	0	Reserved

Table 38-63. USB External Power Control Register (USBEPC) Field Descriptions (continued)

Bit	Field	Value	Description
2	EPENDE		EPEN Drive Enable. This bit specifies whether the USB0EPEN signal is driven or undriven (tristate). When driven, the signal value is specified by the EPEN field. When not driven, the EPEN field is ignored and the USB0EPEN signal is placed in a high-impedance state. The USB0EPEN signal is undriven at reset because the sense of the external power supply enable is unknown. By adding the high-impedance state, system designers can bias the power supply enable to the disabled state using a large resistor (100 kΩ) and later configure and drive the output signal to enable the power supply.
		0	Not Driven. The USB0EPEN signal is high impedance.
		1	Driven. The USB0EPEN signal is driven to the logical value specified by the value of the EPEN field.
1-0	EPEN		External Power Supply Enable Configuration. This bit field specifies and controls the logical value driven on the USB0EPEN signal.
		0h	Power Enable Active Low. The USB0EPEN signal is driven Low if the EPENDE bit is set.
		1h	Power Enable Active High. The USB0EPEN signal is driven High if the EPENDE bit is set.
		2h	Power Enable High if VBUS Low. The USB0EPEN signal is driven High when the A device is not recognized.
		3h	Power Enable High if VBUS High. The USB0EPEN signal is driven High when the A device is recognized.

38.6.3.47 USB External Power Control Raw Interrupt Status Register (USBEPCRIS), offset 0x404

The USB external power control raw interrupt status 32-bit register (USBEPCRIS) specifies the unmasked interrupt status of the two-pin external power interface.

Mode(s): Host Device

USBEPCRIS is shown in Figure 38-59 and described in Table 38-64.

Figure 38-59. USB External Power Control Raw Interrupt Status Register (USBEPCRIS)

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	PF		USB Power Fault Interrupt Status. This bit is cleared by writing a 1 to the PF bit in the USBEPCISC register.
		0	A Power Fault status has been detected.
		1	An interrupt has not occurred.

38.6.3.48 USB External Power Control Interrupt Mask Register (USBEPCIM), offset 0x408

The USB external power control interrupt mask 32-bit register (USBEPCIM) specifies the interrupt mask of the two-pin external power interface.

Mode(s): Host Device

USBEPCIM is shown in Figure 38-59 and described in Table 38-64.

Figure 38-60. USB External Power Control Interrupt Mask Register (USBEPCIM)

31	1	0

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	PF		USB Power Fault Interrupt Status and Clear. This bit is cleared by writing a 1. Clearing this bit also clears the PF bit in the USBEPCISC register.
		0	The PF bits in the USBEPCRIS and USBEPCIM registers are set, providing an interrupt to the interrupt controller.
		1	No interrupt has occurred or the interrupt is masked.

38.6.3.50 USB Device RESUME Raw Interrupt Status Register (USBDRRIS), offset 0x410

The USB device RESUME raw interrupt status register (USBDRRIS) is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

Mode(s): Host Device

USBDRRIS is shown in Figure 38-62 and described in Table 38-67.

Figure 38-62. USB Device RESUME Raw Interrupt Status Register (USBDRRIS)

0	PF		RESUME Interrupt Status This bit is cleared by writing a 1 to the RESUME bit in the USBDRISC register.
		0	A RESUME status has been detected.
		1	An interrupt has not occurred.

38.6.3.51 USB Device RESUME Raw Interrupt Mask Register (USBDRIM), offset 0x414

The USB device RESUME raw interrupt status register (USBDRIM) is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

Mode(s): Host Device

USBDRIM is shown in Figure 38-63 and described in Table 38-68.

Figure 38-63. USB Device RESUME Raw Interrupt Status Register (USBDRRIS)

31	1	0

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	PF		RESUME Interrupt Mask
		0	The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the USBIS register is set).
		1	A detected RESUME does not affect the interrupt status.

38.6.3.52 USB Device RESUME Interrupt Status and Clear Register (USBDRISC), offset 0x418

The USB device RESUME interrupt status and clear register (USBDRRIS) is the raw interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

Mode(s): Host Device

USBDRISC is shown in Figure 38-64 and described in Table 38-69.

Figure 38-64. USB Device RESUME Interrupt Status and Clear Register (USBDRISC)

31	1	0
Reserved		RESUME

31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	RESUME		RESUME Interrupt Status and Clear. This bit is cleared by writing a 1. Clearing this bit also clears the RESUME bit in the USBDRCRIS register.
		0	The RESUME bits in the USBDRRIS and USBDRCIM registers are set, providing an interrupt to the interrupt controller.
		1	No interrupt has occurred or the interrupt is masked.

38.6.3.53 USB General-Purpose Control and Status Register (USBGPCS), offset 0x41C

The USB general-purpose control and status register (USBGPCS) provides the state of the internal ID signal.

When the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the USB General-Purpose Control and Status (USBGPCS) register should be used to connect the ID inputs to fixed levels internally. For proper self-powered device operation, the V_{BUS} value must be monitored to assure that if the Host removes V_{BUS}, the self-powered device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to V_{BUS}.

Mode(s): Host Device

USBGPCS is shown in Figure 38-65 and described in Table 38-70.

Figure 38-65. USB General-Purpose Control and Status Register (USBGPCS)

► CONNECTIVITY MANAGER (CM)

The following chapters describe the Connectivity Manager peripherals.

39.1 Technical Reference Manual Overview

The block diagram for the F2838x device is shown below below in Figure 39-1. This Technical Reference Manual is organized into five major sections:

- C28 SYSTEM RESOURCES

  These chapters describe the C28 CPU subsystem, C28 Boot ROM, device configuration, and other system peripherals.
- ANALOG PERIPHERALS

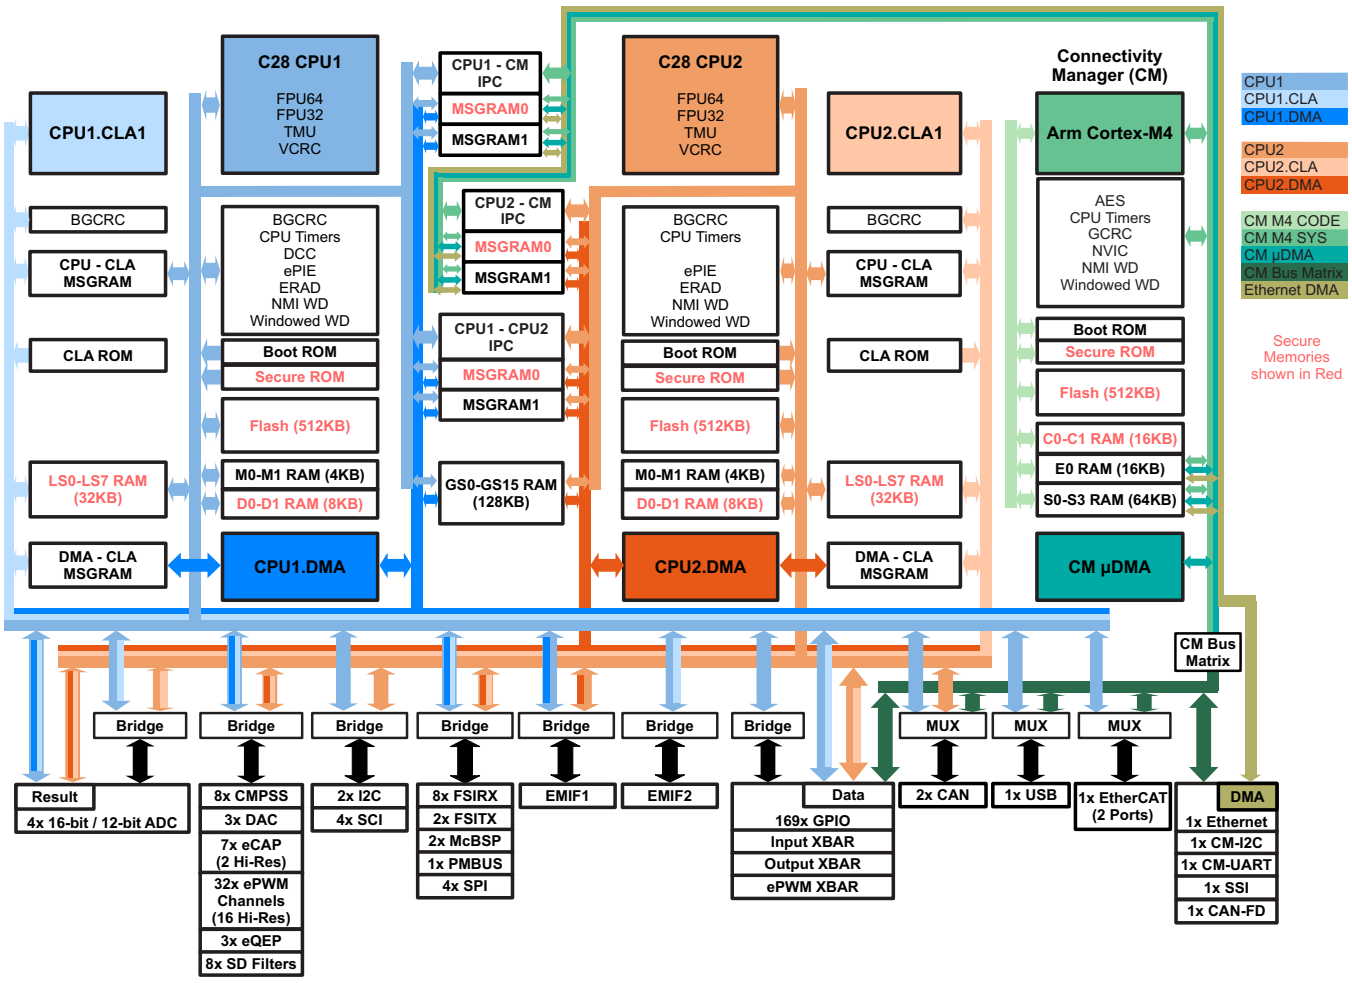
  These chapters describe the Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), Comparator Subsystem (CMPSS), and general analog subsystem configuration.
- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High Resolution Capture (HRCAP), Enhanced Pulse Width Modulator (ePWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.
- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C28 subsystem such as I2C, SCI, FSI, McBSP, PMBUS, and SPI. The CAN, EtherCAT, and USB peripherals are also described in this section and can be assigned to the CM subsystem.
- CONNECTIVITY MANAGER (CM)

  These chapters describe the Connectivity Manager subsystem as well as the AES, GCRC, CM-I2C, CM-UART, SSI, and Ethernet peripherals.

Figure 39-1. F2838x Block Diagram



Connectivity Manager Subsystem

This chapter discusses the Connectivity Manager (CM) architecture and its associated peripherals.

Topic **Page**

40.1 Connectivity Manager Overview

The Delfino™ TMS320F2838x supports dual-core C28x architecture along with a new connectivity manager subsystem. The connectivity manager subsystem is based on the industry standard 32-bit ARM Cortex-M4 CPU and features a wide variety of communication peripherals, including EtherCAT, Ethernet, USB, MCAN (CAN-FD), DCAN, UART, SSI, I2C, and so on. Targeting performance and flexibility, the connectivity manager is based on 125 MHz Cortex-M4 architecture and provides a variety of integrated memories as well as multiple programmable GPIOs. It offers consumers compelling cost-effective solutions by integrating application-specific peripherals, and provides a comprehensive library of software tools which minimize board costs and design-cycle time. Table 40-1 lists the key architectural features of connectivity manager

The primary goals of the Connectivity Manager (CM) are to:

- Allow easy porting of standard communication software stacks from the ARM eco system.
- Allow easy porting of AUTomotive Open System ARchitecture (AUTOSAR) and Micro Controller Abstraction Layer (MCALs) for communication peripherals like DCAN.
- Provide additional communication MIPS.

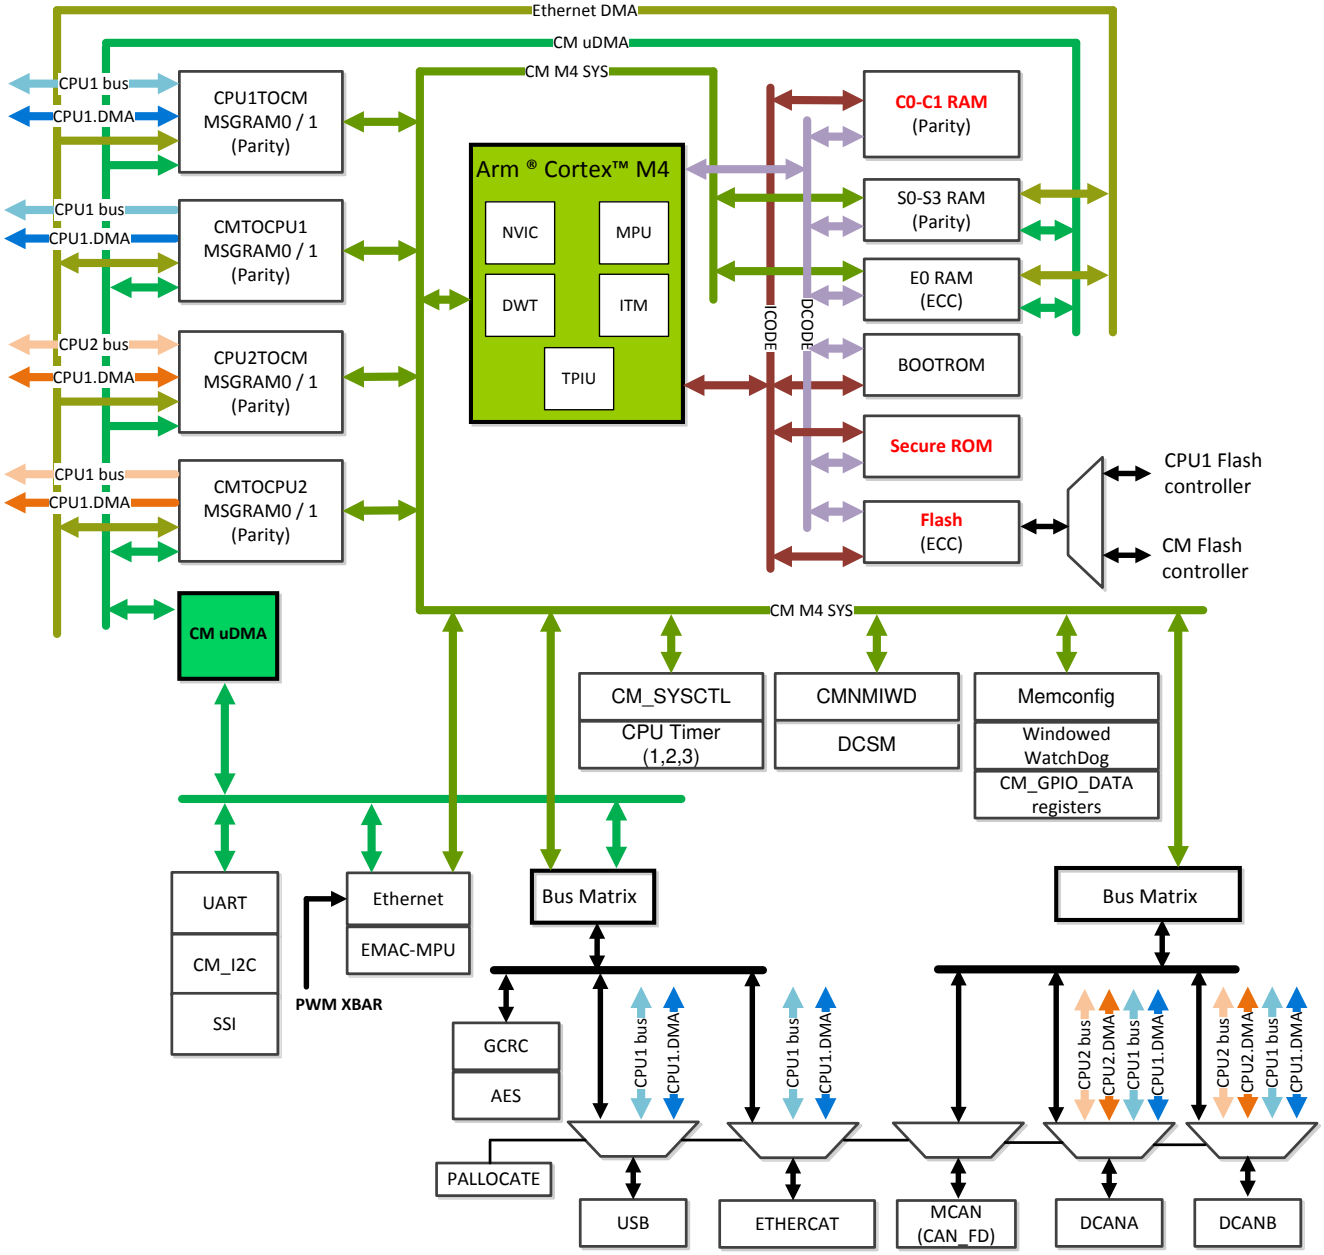
Table 40-1. Connectivity Manager Architectural Features

Feature	Description	CPU1	CPU2
Core	ARM Cortex-M4	NA	NA
Frequency (MHz)	125 MHz	NA	NA
Flash	512KB	Yes	No
RAM	96KB	Yes	Yes
BOOTROM	96KB	No	No
uDMA	1	No	No
DCAN	2	Yes	Yes
EtherCAT	1	Yes	No
USB	1	Yes	No
MCAN (CAN-FD)	1	No	No
Ethernet	1	No	No
SSI	1	No	No
UART	1	No	No
I2C	1	No	No
AES	1	No	No
GCRC	1	No	No
Timer	3	No	No
Windowed watchdog	1	No	No

40.2 Connectivity Manager Functional Block Diagram

The figure below shows the functional block diagram and associated peripherals of the connectivity manager.

Figure 40-1. Connectivity Manager Block Diagram



40.3 ARM Cortex-M4 Processor Core Overview

The ARM® Cortex™-M4 processor includes the following:

- 32-bit ARM Cortex-M4 architecture optimized for small-footprint embedded applications
- Cortex-M4 CPU can be operated at maximum frequency of 125-MHz
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed, 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications

  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast multiplier
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Migration from the ARM7 processor family for better performance and power efficiency

See the ARM® Cortex®M4 Processor Technical Reference Manual ® for more information.

Connectivity Manager - System Control and Interrupts

This section describes the system-level functionality of the TMS320F2838x Connectivity Manager CPU.

Topic **Page**

41.1 Introduction

This section provides discussions that include configuration of the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

41.2 Reset

The types and effects of the different reset sources on the CM subsystem are discussed here. Reset for the CM subsystem is controlled by CPU1 and it is held in reset unless the user's application code on CPU1 releases the CM out of reset by writing '0' to the RESET bit of the CMRESCTL register. After updating the RESET bit, the user's software can read the RESETSTS bit of the CMRESCTL register to check the reset status of the CM. A Write to the CMRESCTL register is protected by KEY; therefore the user must put the correct value (0xA5A5) in the KEY field to make any updates to this register. Because of this, the user must always perform a 32-bit write to this register.

Below are the different reset sources on the CM subsystem.

41.2.1 CPU1 $\overline{\text{SYSRS}}$

Any time the CPU1 subsystem gets reset and asserts a CPU1.$\overline{\text{SYSRS}}$ signal, it resets the CM subsystem as well. The CM subsystem is held in reset unless the user application code on CPU1 releases CM out of reset by writing '0' to the RESET bit of the CMRESCTL register.

41.2.2 System Reset Request (CMSYSRESETREQ)

User software running on the CM can initiate a reset to the CM subsystem by writing '1' to the SYSRESETREQ bit of the AIRCR register of Cortex-M4. This action resets almost all the logic on the CM except for debug.

After this reset, the CMSYSRESETREQ bit in the CMRESC register will be set. Software can read this bit to determine the cause of the reset and clear the status by writing '1' into the corresponding bit in the CMRESCCLR register.

NOTE: Cortex-M4 also has software reset by name VECTRESET. VECTRESET only resets the Cortex-M4 core and not other logic in CM subsystem hence could cause unexpected behavior. User should avoid using this reset.

41.2.3 CM NMI Watchdog Reset (CMNMIWDRSTn)

Like CPU1/CPU2, the CM has its own non-maskable interrupt (NMI) module that captures the hardware errors in the CM subsystem as well as some of device level error. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This reset activity resets almost all the logic on the CM except for debug. The CMNMIWDRSTn bit can trigger an NMI or interrupt on CPU1 (depending on the configuration of the CMNMIWDRST bit field in the CMTOCPU1NMICTL register).

After this reset, the CMNMIWDRSTn bit in the CMRESC register will be set. Software can read this bit to determine the cause of the reset and clear the status by writing '1' into the corresponding bit in the CMRESCCLR register.

41.2.4 CM Secure Code Copy Reset (CMSCCRESETn)

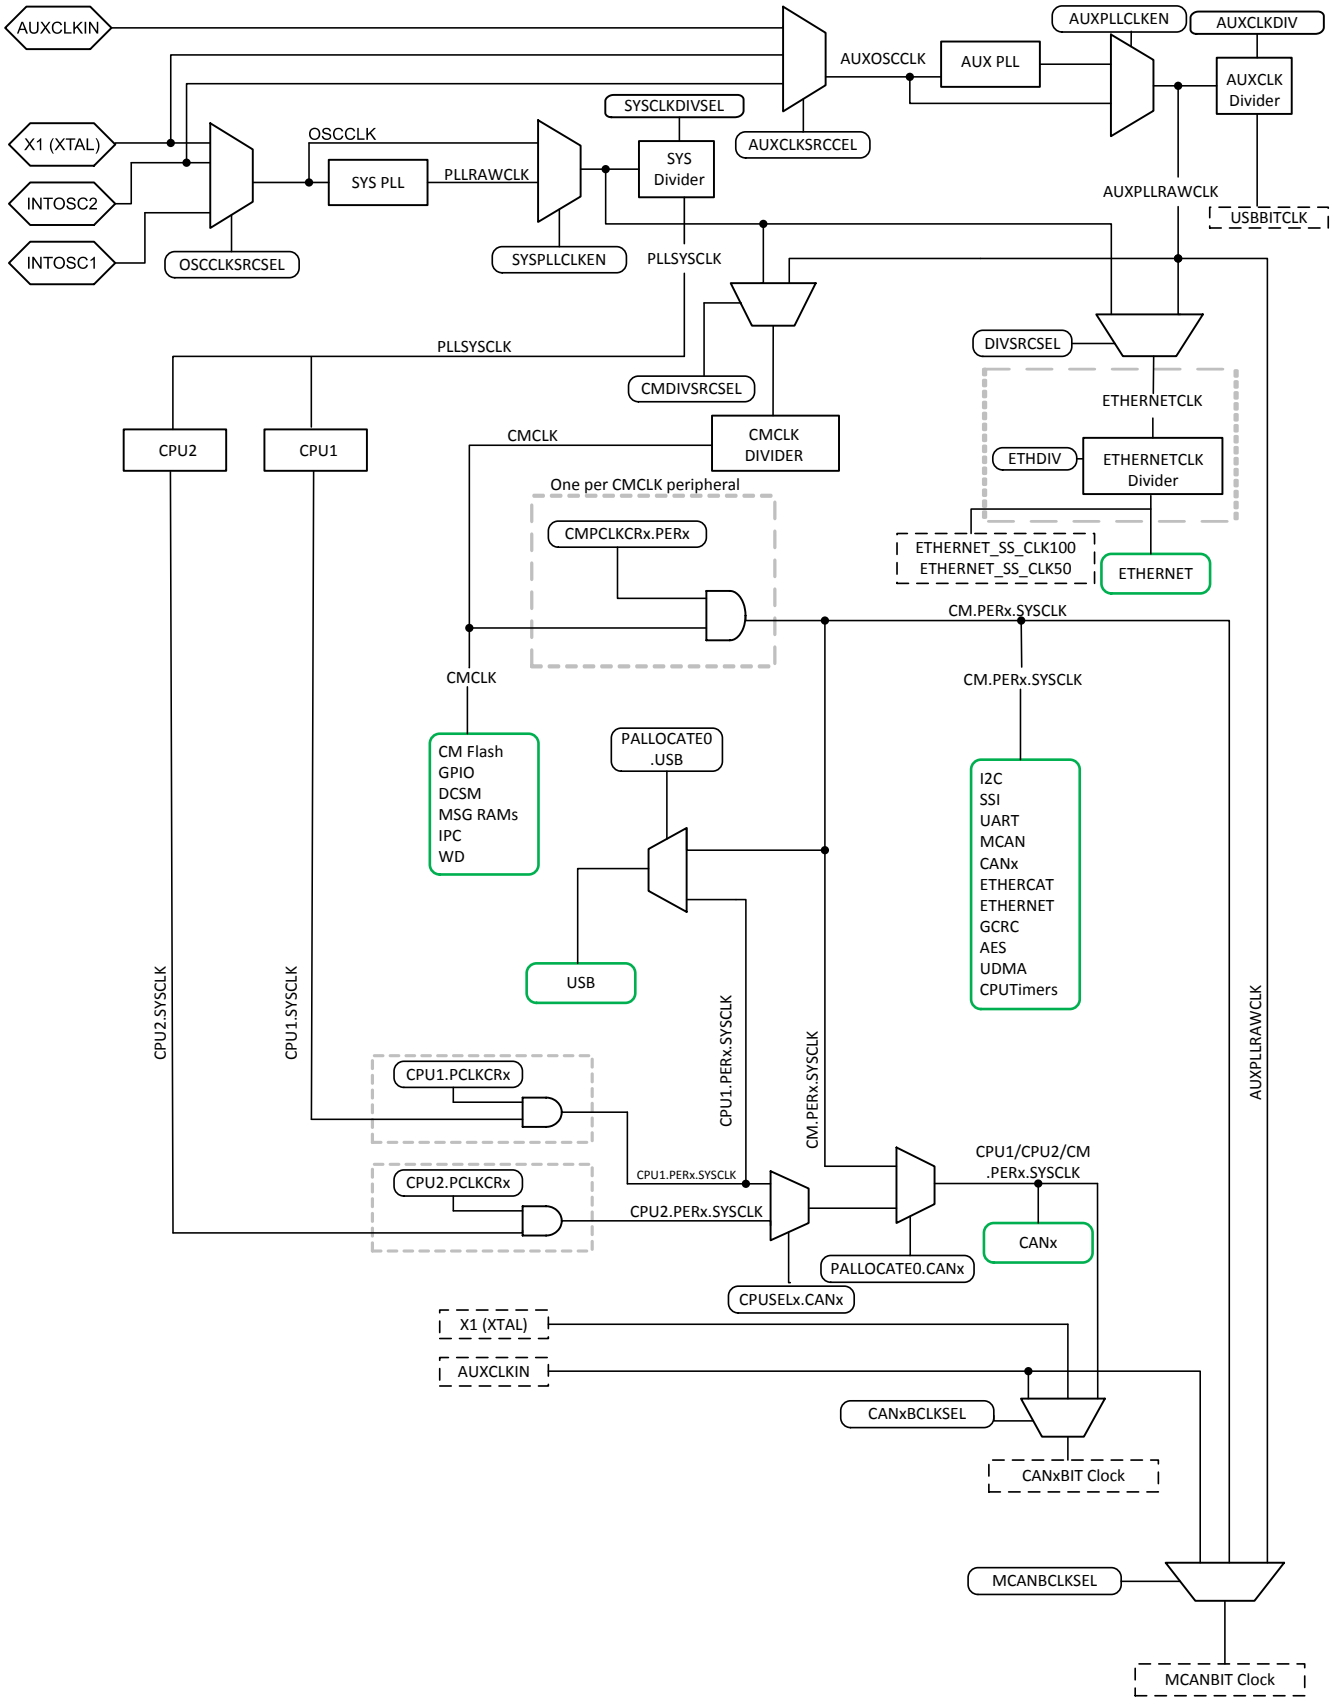
The dual-zone code security module (DCSM) on this device locks read access to secure memories including ROM. To facilitate CRC checks, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a secure copy or CRC function, the DCSM triggers a reset. This reset on the CM is the same as the CM System Reset.

After this reset, the CMEOLRESETn bit in the CMRESC register will be set. Software can read this bit to determine the cause of the reset and clear the status by writing '1' into corresponding bit in the CMRESCCLR register.

41.3 CM Clocking

This section explains the clock sources and clock domains on the Connectivity Manager, and how to configure them for application use. The figure below provides an overview of the CM clocking system.

Figure 41-1. CM Clocking System



41.3.1 CM Clock Sources

Clock sources for C28x and the CM are the same. Refer to Section 3.7.1 for more information.

41.3.2 CM Derived Clocks

Derived clock sources for the Connectivity Manager are the same as C28x derived clocks. Refer to Section 3.7.2 for more information.

41.3.3 CM Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider. In addition to clock domains defined in the Device Clock Domains for C28x System (refer Section 41.3.3) the clock domains below are derived specifically for the CM (Cortex-M4) Subsystem.

41.3.3.1 Connectivity Manager Clock (CMCLK)

The CM clock is derived from PLLSYSCLK or AUXPLLRAWCLK and then divided down by the CMCLK divider. This clock is asynchronous to the CPU1/CPU2 system clock. This clock is used by the Cortex-M4 CPU (CM), GPIO, DCSM, Message RAMs, IPC and Watch Dog.

41.3.3.2 CM Peripheral Sub-System Clock (CM.PERx.SYSCLK)

This clock is the same as CMCLK, where each peripheral clock has its own independent clock gating which is controlled by the CMPCLKCRx registers.

41.3.3.3 MCAN Bit Clock

The required frequency tolerance for the MCAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1. Since the main system clock (in the form of CM.PERx.SYSCLK) may not be precise enough, the bit clock can also be connected to AUXCLKIN or AUXPLLRAWCLK via the CLKSRCCTL2.MCANxBITCLKSEL bit.

41.3.4 CM Clock Connectivity

The table below provides details on the CM clock connections.

Table 41-1. CM Clock Connections

Clock Domain	Module Name
CMCLK	GPIO DCSM Message RAMs IPC Watch Dog
CM.PERx.SYSCLK	I2C SSI UART MCANA ETHERCAT ETHERNET GCRC AESLIP UDMA CPUTIMER 0 - 2 USB CANA - B
CAN Bit Clock	CANA - B
MCAN Bit Clock	MCANA

41.4 SysTick

Cortex-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer; the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNT bit in the STCTRL control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the STRELOAD register on the next clock edge, then decrements on subsequent clocks. Clearing the STRELOAD register disables the counter on the next wrap. When the counter reaches zero, the COUNT status bit is set. The COUNT bit clears on reads.

Writing to the STCURRENT register clears the register and the COUNT status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on the processor clock. If this clock signal is stopped for low power mode, the SysTick counter stops. Ensure software uses aligned word accesses to access the SysTick registers.

Note: When the processor is halted for debugging, the counter does not decrement.

41.5 Watchdog Timer

The Connectivity Manager (CM) has one watchdog (also referred to as windowed watchdog) timer. The functionality of this watchdog timer is the same as the one used on CPUx subsystems. Refer to the Watchdog Timers section in the *C28x System Control* chapter for details about this module. Following are some differences in the configuration of the watchdog timer on the CM vs CPUx.

- The Watchdog timer on CM is disabled by default. Software needs to clear the WDDIS bit in the WDCR register to enable the watchdog.
- Whenever the watchdog counter (WDCR) overflows or an incorrect value is written to WDCR[WDCHK], an NMI gets generated (not reset or interrupt such as CPUx watchdog timers) to the CMNMIWD module. If software is not able to service the NMI, then the NMIWD module will trigger a reset to the CM.

The CM watchdog timer counter stops incrementing when the Cortex-M4 is halted during the debug session.

41.6 Exceptions and NMI

This section provides details about interrupts and exception handling supported by the CM subsystem. Both the CM and C28 subsystems each have an independent NMI module which captures various exceptions that can occur in the system and trigger an NMI to the respective CPU core.

This device has exception capturing and handling ability which enables the device to be used in many safety-critical applications. Device run-time exceptions that can be detected and acted upon include clock failure detection, memory access error detection, memory uncorrectable error, flash uncorrectable error, MCAN uncorrectable error, NMI watchdog error, EtherCAT error, bus fault detection, and interrupt handler address mismatch errors. This device also supports back-to-back, non-maskable interrupt handling capability, along with highly configurable peripheral interrupt handling.

The CM subsystem is built around the Cortex-M4 ARM core and includes the Nested Vectored Interrupt Controller (NVIC) module, while the C28 subsystem is built around the C28x core and includes the peripheral interrupt expansion (PIE) module. This enables the user to configure, handle, and serve interrupt requests from different subsystem peripherals and handle various exceptions that can occur in the device during its operation. Exception handling on the CM subsystem is built such that it will be able to identify and handle the errors, even if the C28 subsystem fails to handle its exceptions.

41.6.1 CM Subsystem Nested Vectored Interrupt Controller

Refer to Section 41.7 for a detailed overview of the NVIC.

As part of the CM subsystem, the Cortex-M4 NVIC handles exceptions that can occur on the CM subsystem. The Cortex-M4 NVIC module supports a non-maskable interrupt, which has higher priority than all other NVIC-supported interrupts or exceptions. The CM subsystem's non-maskable interrupt module (CMNMI) is responsible for generating this non-maskable interrupt to the Cortex-M4 CPU core in the CM subsystem. Refer to Section 41.6.3 for more details on NMI handling.

The NVIC supports a HARDFAULT exception interrupt which has higher priority than any programmable interrupts but less priority than an NMI. Other programmable exceptions supported by the NVIC are memory management faults, bus faults, and usage fault programmable exceptions. These programmable exceptions are disabled by default and the system errors which can cause these exception events end up triggering a HARDFAULT exception. Section 41.6.2 provides details on the events that cause these exceptions.

On power-up and any reset that resets the CM CPU, the NVIC is mapped to the address of 0x0000 0000 in ROM. The M-Boot ROM installs predefined interrupt handlers in the default NVIC table as needed for the boot ROM execution and C28. Once the user application is started by boot ROM, the interrupt handlers should have their own NVIC vector table and map the NVIC base address to user locations. If users fail to remap the NVIC to their application needs, any interrupt that occurs while the application is executing ends up calling interrupt and exception handlers installed by boot ROM. Refer to the *Boot ROM* chapter for more details on boot ROM handlers in the NVIC.

41.6.2 CM Subsystem Exceptions Handling

The table below provides information on different exceptions supported by NVIC on the CM subsystem.

Table 41-2. CM Subsystem Exceptions

Exception Type	Vector Number	Priority	Description
Reset	1	-3 (highest)	This exception is invoked on power up and on any other reset. On the first instruction, Reset drops to the lowest priority and then is called the base level of activation. This exception is asynchronous.
Non-Maskable Interrupt(NMI)	2	-2	A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the Interrupt Control and State (INTCTRL) register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
Hard Fault	3	-1	This exception is caused by all classes of Fault when the fault cannot activate due to priority or the configurable fault handler has been disabled. This exception is synchronous.
Memory Management	4	Configurable	This exception is caused by an MPU mismatch, including access violation and no match. This exception is synchronous.
Bus Fault	5	Configurable	A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.
Usage Fault	6	Configurable	This exception is caused by a usage fault, such as an undefined instruction executed or an illegal state transition attempt. This exception is synchronous.

From the above exceptions, the NMI and bus faults are generated by the digital subsystem, whereas memory management errors are generated internally by the M4 MPU.

Bus Fault Exceptions:

For all uncorrectable memory errors during M4 CPU reads or writes (address, parity or double data error), HRESP-based, and HREADY-based error, responses will be generated by the memory C28 logic.

Write Accesses:

When an HRESP-error is generated for write accesses, if the intended write was a stack push, STKERR status will be set by the NVIC upon seeing the bus fault indication for the stack push operation. If the application so prefers, it can treat a STKERR as a low priority exception and pend the same, except when stacking for an exception.

Read Accesses:

For all uncorrectable errors during reads, the same HRESP-error indication will be generated. The M4 core will use this error indication in the following manner:

- For bus errors during normal data reads, the M4 would generate a bus fault, but the application can treat this as a lower priority, thereby enabling a higher priority exception to be serviced by the CPU. As an example, there may be a bus fault in a user thread and still the CPU could service an interrupt to handle critical interrupts - the bus fault can be handled afterwards. But if the read occurs during an ISR bus fault, it will be treated as a hard fault, since it is in code for an exception that should never fault.
- For bus errors during stack pops, the NVIC will set the UNSTKERR status indication and the M4 will generate a bus fault
- For bus errors during vector table reads, the NVIC will set VECTTBL and the M4 will generate a bus fault. If there is a double fault when the bus fault handler tries to read the vector, the M4 CPU will enter a LOCKUP condition. In this condition, the M4 WDT timers will time out and issue a reset to the system.

- For bus errors during fetches, even if the M4 sees an error response, it will not internally bus fault unless the CPU is decoding the erroneous instruction fetched

For more details on how the remaining exceptions are generated by the Cortex-M4 CPU, refer to the Section 41.7

Refer to the *Boot ROM* chapter for more details on how boot ROM handles HARDFAULT exceptions if it occurs during boot ROM execution.

On the CM subsystem all the below errors generate a BUSFAULT.

- RAMUNCERR - RAM Uncorrectable error. This is a double bit error generated by the RAM wrapper logic as a bus error.
- RAMACCVIOL - Ram Access violation.

41.6.3 CM Subsystem Non-Maskable Interrupt (CMNMI) Module

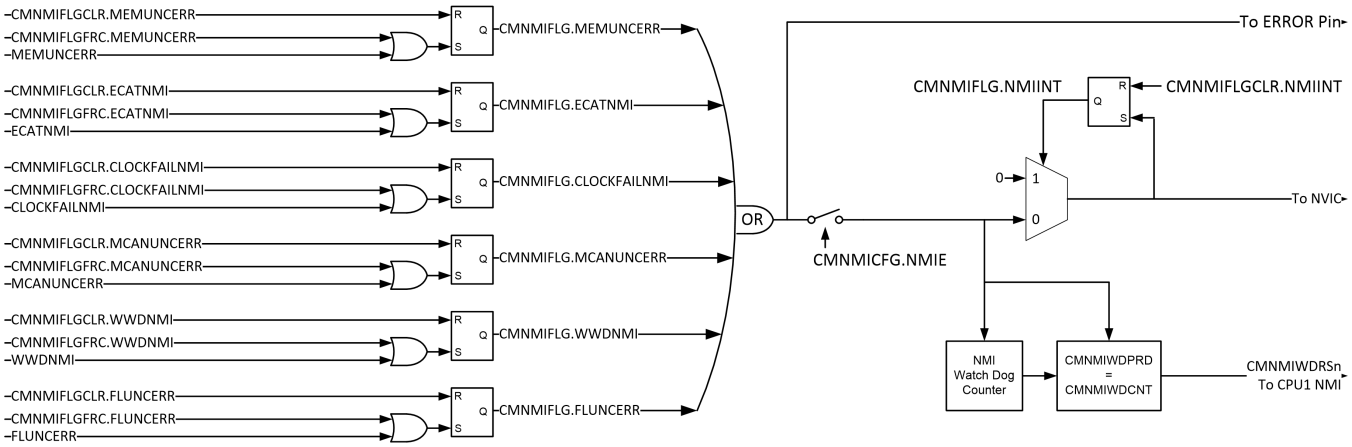
The CM subsystem has the capability of detecting all serious errors that could occur in the entire system including all the subsystems, and inform the main CPU core about the error. An NMI exception to the M4 CPU on the CM subsystem will be generated only when at least one or more of the below NMI error sources become active. More details on each of the sources is given in Section 41.6.3.1 and the descriptions in the CMNMIFLG register.

1. RAM/ROM uncorrectable error
2. Reset request from the EtherCAT
3. Clock failure
4. MCAN uncorrectable error
5. CM windowed watchdog timed out
6. Flash uncorrectable error

All these NMI sources are "OR-ed" to generate the NMI input to the M4 NVIC. The NMI triggers a CMNMIWD counter running at the CM subsystem frequency. The CMNMIWD counter will stop counting only if all the pending NMIs are acknowledged by clearing the pending flags in the CMNMIFLG register. If the pending NMI is not acknowledged before the CMNMIWD counter reaches the value programmed in the NMI Watchdog period register (CMNMIWDPRD), an NMIWD reset is generated to the CM subsystem, which will reset the entire device.

Figure 41-2 shows different sources that can trigger an NMI to the Cortex-M4 on the CM subsystem and the registers associated with them.

Figure 41-2. CM Subsystem NMI Sources and NMIWD



All the NMI sources shown in Figure 41-2 are enabled by default on reset. CMNMICFG.NMIE is disabled on reset and needs to be enabled by setting it to 1.

Whenever an NMI signal is generated, the respective bit in the CMNMIFLG register is set. To aid in debug, development, and testing, a CMNMIFLGFRC register is provided. Setting these bits in this register will force the NMI to the CPU core as shown in Figure 41-2. Refer to the CMNMIFLGFRC register for more details. When an NMI is triggered to the CM CPU, a CMNMIWD counter is triggered and begins counting. It will reset the device when the CMNMIWD counter reaches the programmed CMNMIWD period value. The CMNMIWD counter will stop counting and reset back to zero once all the set CMNMIFLG bits and the CMNMIINT flag bit in the CMNMIFLG register are cleared.

41.6.3.1 CM Subsystem NMI Sources

This section explains all the possible NMI sources on the CM subsystem.

41.6.3.1.1 RAM/ROM Uncorrectable Error

This NMI is triggered if an error occurred on a RAM/ROM access (including peripheral RAMs) by any master.

41.6.3.1.2 Reset Request from EtherCAT

This NMI is triggered if a reset request was sent from the EtherCAT module.

41.6.3.1.3 Clock Fail Condition

A main oscillator verification circuit is provided that generates an error condition if the oscillator is running too fast or too slow or goes missing. This logic is referred to as Missing Clock Detection. When a missing clock error is generated, the CLOCKFAIL bit (bit 1) of the CMNMIFLG register is set, the clock source is switched to the 10 MHz internal oscillator, and the PLL is bypassed.

The CLOCKFAIL NMI is triggered to both the CM and C28 subsystems. Since this NMI source is enabled by default on power up, it makes it necessary for boot ROM to handle this NMI. Refer to the *Boot ROM* chapter of this document for more details on how boot ROM handles this NMI.

41.6.3.1.4 MCAN Uncorrectable Error

This NMI is triggered if an error occurred on a MCAN message RAM access.

41.6.3.1.5 CM Windowed Watchdog Timed Out

This NMI is triggered if the CM's windowed watchdog times out.

41.6.3.1.6 Flash Uncorrectable Error

This NMI is triggered if an error occurred on a CM Flash access.

41.6.3.2 CM Subsystem NMIWD Module

As explained previously, the CM subsystem is equipped with an NMI Watchdog module whose function is to make sure that a triggered non-maskable interrupt is handled by user software. This can be achieved by clearing the error conditions and clearing the respective flags in the CMNMIFLG register or by acknowledging the NMI and gracefully shutting down the system. If none of the actions mentioned are taken, then the CMNMIWD counter keeps counting until the counter value reaches the CMNMIWD period register value. An CMNMIWD reset will then be generated, which will reset the entire device.

As shown in Figure 41-2, any enabled NMI source can set the CMNMIINT respective bit in CMNMIFLG register, which will trigger an NMI to the CPU and start the CMNMIWD counter. The CMNMIWD counter will keep counting as long as the CMNMIINT bit of the CMNMIFLG register is not cleared or a reset is generated.

The CMNMIWD counter is clocked by the M4 system clock. The CMNMIWDPRD register, which is the CMNMI Watchdog Period register, can be programmed with a period limit as per user requirements which sets the clock cycle limit required for software to handle or acknowledge the NMI. A timeout condition that generates the NMI watchdog reset means that the counter value of the CMNMIWDCNT register reached the value programmed in the period register, CMNMIWDPRD.

41.6.3.2.1 Emulation Considerations

When the Cortex-M4 CPU is suspended (in debug halt), the NMI watchdog counter will be suspended.

41.6.3.3 Handling of CMNMI

User software must clear all the flag bits which are set in the CMNMIFLG register before clearing CMNMIINT, bit 0 of the CMNMIFLG register. If the user clears the CMNMIINT bit in the CMNMIFLG register before clearing all the individual flag bits, as soon as the CMNMIINT bit is cleared it will be set back to "1" again. This will generate another back-to-back NMI to the CM subsytem's CPU, and the CMNMIWD counter will start counting again.

41.6.4 CM Interrupts/NMI to CPU1/CPU2

Table 41-3 and Table 41-4 show the various Interrupts and NMI generated to C28's CPU1 and CPU2 respectively.

41.7 Nested Vectored Interrupt Controller (NVIC)

The NVIC multiplexes interrupts from various peripherals into the CM interrupt lines. In essence, the NVIC is the Peripheral Interrupt Expansion (PIE) equivalent for the CM. The features supported by the NVIC are as follows:

- 80 interrupts
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling
- Level and pulse detection of interrupt signals
- Dynamic reprioritization of interrupts
- Grouping of priority values into group priority and subpriority fields
- Interrupt tail-chaining
- An external non-maskable interrupt

The CM automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

41.7.1 Level-Sensitive and Pulse Interrupts

The CM supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the CM clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the CM enters the ISR, it automatically removes the pending state from the interrupt (see *Hardware and Software Control of Interrupts* for more information). For a level-sensitive interrupt, if the signal is not deasserted before the CM returns from the ISR, the interrupt becomes pending again, and the CM must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

41.7.2 Hardware and Software Control of Interrupts

The CM latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the Software Trigger Interrupt (STIR) register to make a software-generated Interrupt pending. See the NVIC_ISPRx register or STIR register.

A pending interrupt remains pending until one of the following:

- The CM enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the CM returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the CM to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the CM returns from the ISR the state of the interrupt changes to pending, which might cause the CM to immediately re-enter the ISR. If the interrupt signal is not pulsed while the CM is in the ISR, when the CM returns from the ISR, the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

41.7.3 NVIC Registers Access

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the Configuration and Control (CCR) register. Any other unprivileged mode access causes a bus fault. Before accessing the registers:

- Ensure software uses correctly aligned register accesses. The CM does not support unaligned accesses to NVIC registers.
- Be aware that an interrupt can enter the pending state even if it is disabled.
- Before programming the VTOR register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts

41.8 32-Bit CM CPU Timers 0/1/2

The Connectivity Manager has three CPU timers, each operating on the CMCLK and generating an interrupt at certain periodic interval which is determined by the TDDR and TPRD register settings. Each timer operates at a clock period which equals:
TIMER_CLOCK_PERIOD = CMCLK_PERIOD x (TDDR+1)

Each timer generates an interrupt when it reaches 0, whose period equals:
TIMER_INTERRUPT_PERIOD = TIMER_CLOCK_PERIOD x (PRD+1)

Upon the timer reaching zero, the period value is reloaded and the sequence repeats. The timer can be stopped/started by writing a 1/0 to the TCR.TSS bit. The behavior of the timer on a CPU halt (debug halt) is determined by the "FREE, SOFT" bits of the TCR register.

The figures below show the timer clock periods and the timer interrupt periods.

Figure 41-3. CM CPU-Timers

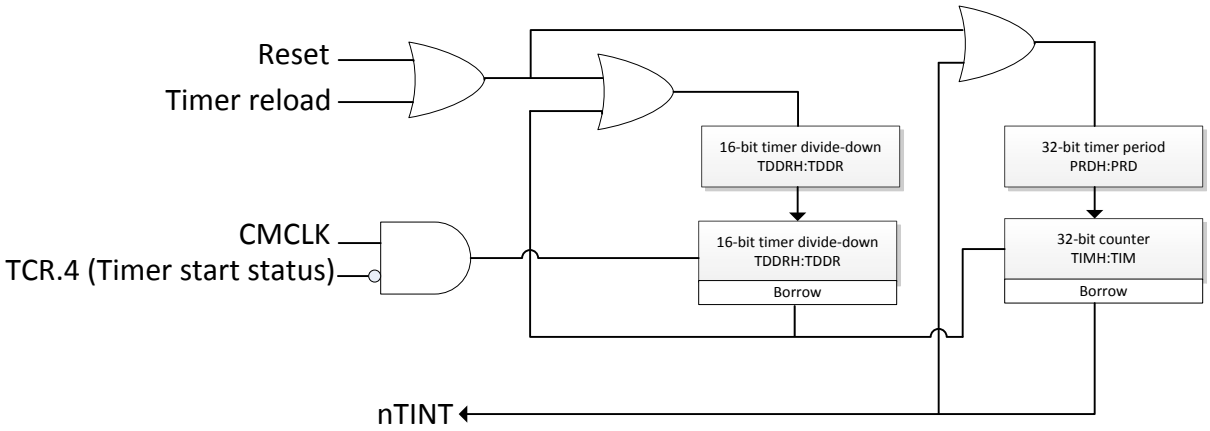

Figure 41-4. CM CPU-Timers Interrupt Signals

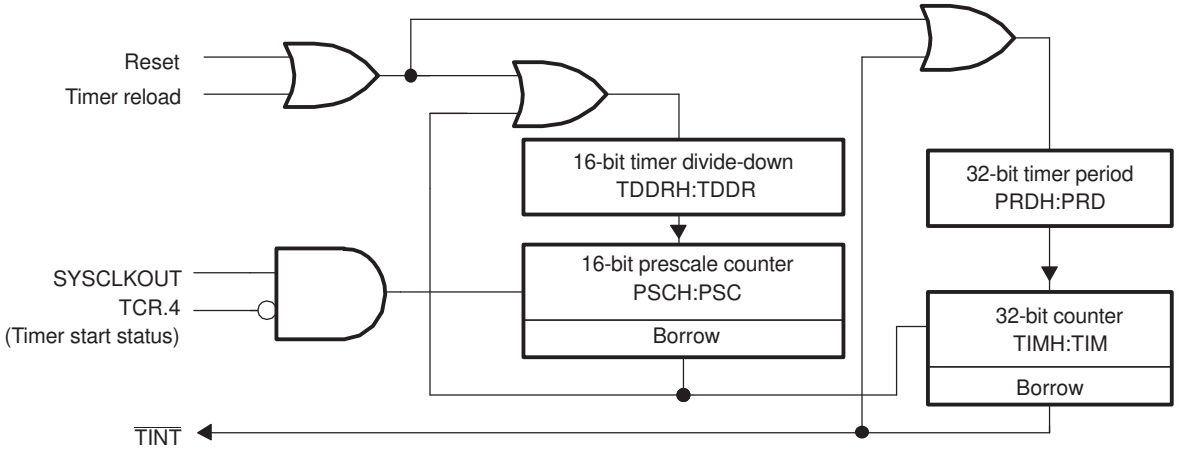


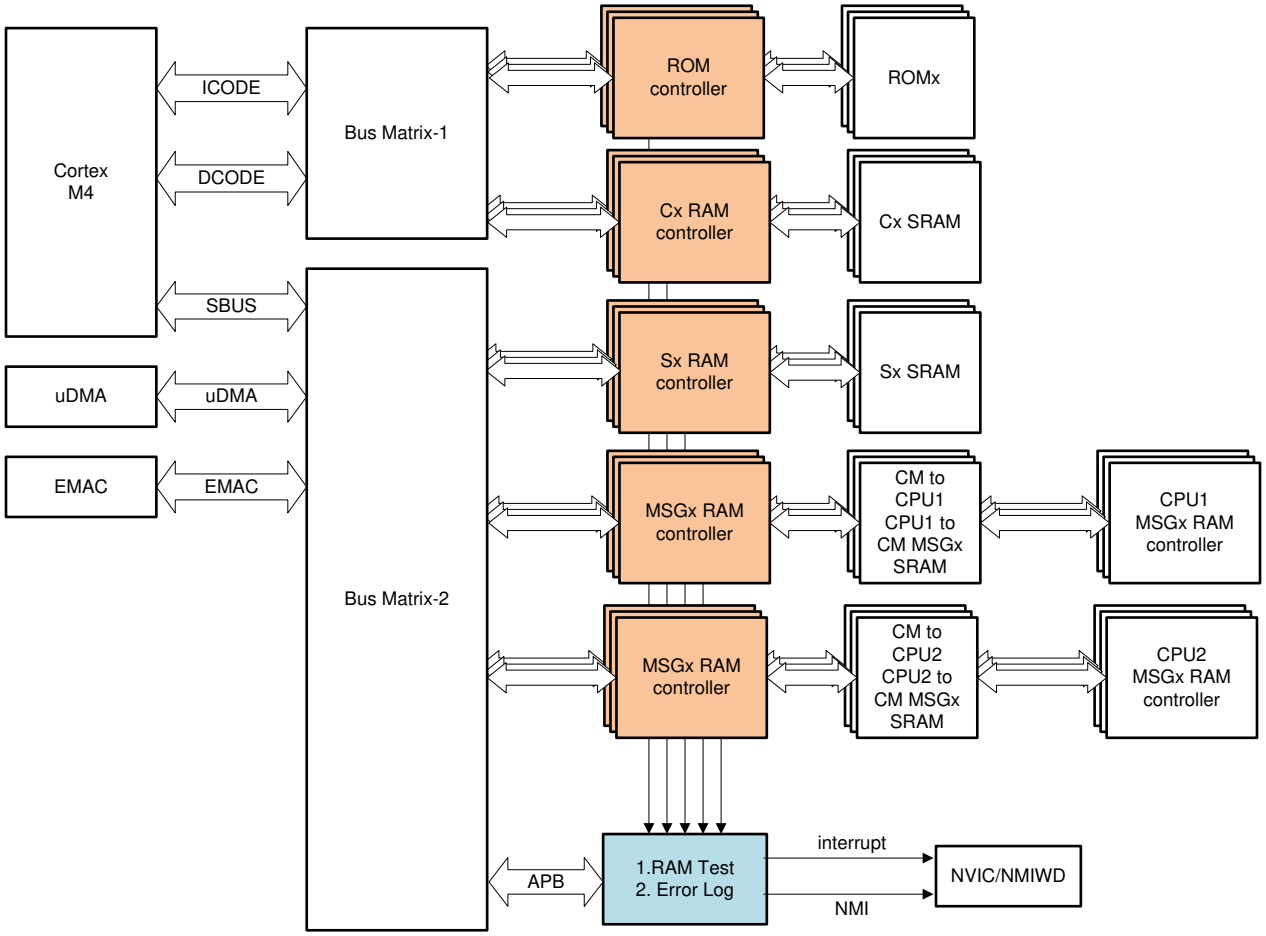
41.9 Memory Controller Module

On the CM subsystem, the RAMs have different characteristics. Some are:

- Dedicated to Cortex M4, accessible from ICODE and DCODE bus only (C0/C1 RAM)
- Shared between Cortex M4, µDMA and other masters in the CM subsystem (Sx RAMs, E0 RAM)
- Used to send and receive messages between the CM and CPU1/CPU2 subsystems (MSGRAM)

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. On the CM subsystemm, only E0 RAMs are enabled with the ECC feature (both data and address). All other RAMs (including MSGRAMs) are enabled with the PARITY (both data and address) feature. C0 and C1 RAMs can be configured as secure RAM. Each RAM has its own controller which takes care of the access protection/security related checks and ECC/Parity features for that RAM. The figure below shows the configuration of these RAMs.

Figure 41-5. CM Memory Block Diagram



41.9.1 Functional Description

This section further defines and discusses different types of memories on the CM subsystem and other features of the SRAM controller.

41.9.1.1 Dedicated RAM

C0 and C1 are dedicated RAMs on the CM subsystem. These RAMs are connected to the ICODE and DOCDE bus of Cortex-M4; hence, only Cortex-M4 has access to these RAMs. These RAMs can be used for timing critical code andthey are also parity protected. If needed in the application, the user can configure these RAMs as secure RAM. Refer to the DCSM section for more information about security.

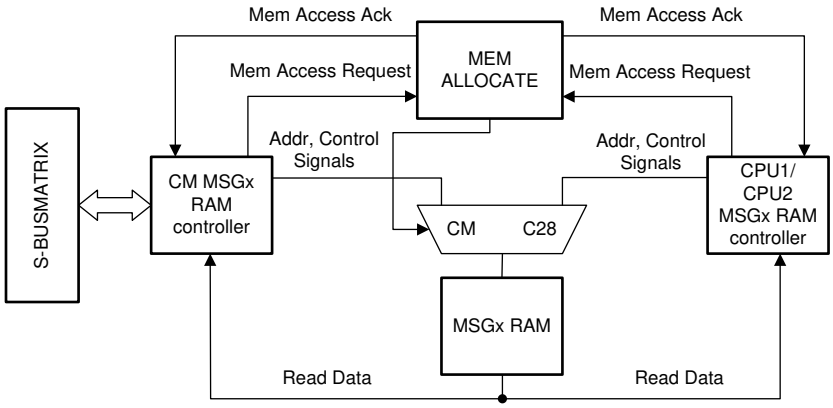
41.9.1.2 Shared RAM

Shared RAMs are connected to the system bus and are accessible from all the masters (Cortex-M4, µDMA and EMAC) on the CM subsystem. On this device, the CM subsystem has five blocks of shared RAMs. Four of these are parity-protected (Sx) and one block is ECC protected (E0). The user can use the E0 RAM block for safety critical code or data-like stack or interrupt handlers.

41.9.1.3 MSG RAM

MSG RAMs are connected to the system bus and are accessible from all the masters (Cortex-M4, uDMA and EMAC) on the CM subsystem. These RAMs are also accessible from the CPU1/CPU2 subsystem (different MSG RAMs for CPU1 and CPU2) and therefore is used for message/data exchange between the CM and CPU1/CPU2 subsystems. MSG RAMs are parity protected. MSG RAMs are also referred to as IPC (inter processor communication) RAMs because these are used for communication between different subsystems. MSG RAMs do not have fetch access and cannot be used for code. On this device, the CM subsystem is asynchronous to the CPU1/CPU2 subsystem and both have access to MSG RAMs. Specific logic (mem allocate logic) is implemented to arbitrate the access from different subsystems. At any given time only one master access is connected to the MSG RAM and Mem allocate logic manages switching of MSGx RAM between C28 and CM RAM controllers.

Figure 41-6. Mem allocate logic



Upon detecting valid access, the AM controller generates a memory access request to mem allocate logic, and then waits for memory allocate logic to acknowledge. Mem Allocate logic acknowledges only after Memory is switched to the requested RAM controller. Upon detecting acknowledge, the RAM controller initiates the memory access. Mem allocate logic arbitrates accesses using round robin priority. Simultaneous access from both masters will result additional latency due to round robin prioritization, as accesses are serviced alternately and latency is introduced due to synchronization. The user application should use the IPC mechanism to avoid simultaneous accesses.

Two sets of message RAMs are defined to overcome latency issues in case of multiple threads running on CM. One is Cortex-M4 writing/reading a message and another master such as µDMA or EMAC DMA writing or reading the message at the same time.

The message RAMs are:

- CMTOCPU1MSGRAM0 (no access from CPU2)
- CMTOCPU1MSGRAM1 (no access from CPU2)
- CPU1TOCMMSGRAM0 (no access from CPU2)
- CPU1TOCMMSGRAM1 (no access from CPU2)
- CMTOCPU2MSGRAM0 (no access from CPU1)
- CMTOCPU2MSGRAM1 (no access from CPU1)
- CPU2TOCMMSGRAM0 (no access from CPU1)
- CPU2TOCMMSGRAM1 (no access from CPU1)

Access permissions to MSG RAMs are hard-coded in functional mode.

The following table lists the allowed accesses to Message RAMs in functional mode.

Table 41-6. CM Message RAM accesses

Message RAM	Cortex-M4	uDMA	EMAC	CPUx	CPUx.DMA
CMTOCPUxMSGRAM0	RD/WR	RD/WR	RD/WR	RD	RD
CMTOCPUxMSGRAM1	RD/WR	RD/WR	RD/WR	RD	RD
CPUxTOCMMSGRAM0	RD	RD	RD	WR	WR
CPUxTOCMMSGRAM1	RD	RD	RD	WR	WR

41.9.1.4 ROM

On this device ROMs are parity protected, and the SRAM controller is used for ROM accesses as well. Like dedicated RAMs, ROMs are also connected to the ICODE and DCODE bus and are programmed with TI code.

41.9.1.5 Interleaving

On the CM subsystem all the RAM and ROM use interleaving techniques to minimize the latencies, especially under scenarios where multiple bus masters are simultaneously trying to access data from a memory block.

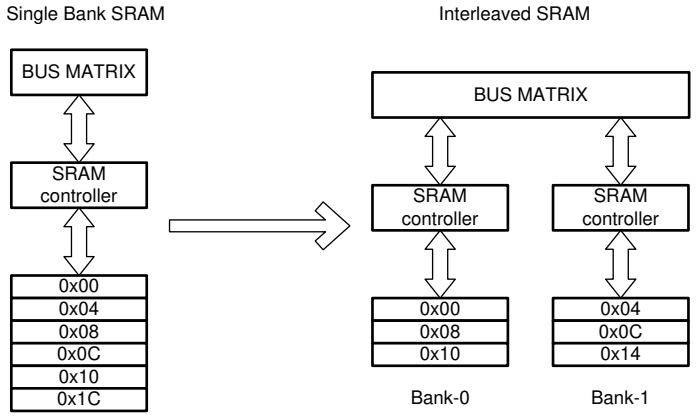
These scenarios are common on CM subsystem. Examples are as follows:

- Sx memories: Cortex-M4 loads the data into its registers for processing while EMAC dumps the received data to memory
- Cx memories: Simultaneous data and instruction fetches

Note that interleaving does not always improve the throughput compared to single bank implementation.

To implement interleaving, a single block of memory is divided into two separate equal physical blocks of half the size and only alternate 32-bit words are stored in each bank. The following diagram shows how data is arranged with interleaving.

Figure 41-7. Interleaving



In dual-bank implementation, even and odd 32-bit word addresses are decoded separately and routed to the appropriate bank. This allows simultaneous accesses from two bus masters to these banks if accesses are not to the same bank; that is, two accesses are serviced in one cycle.

41.9.1.6 Access Arbitration

On the CM subsystem, accesses to all shared RAMs (except MSG RAMs) are arbitrated with fixed priority. The Cortex-M4 system bus has high priority over any other access to ensure no wastage of MIPs. Arbitration is handled by the Arm Bus matrix component and not part of the SRAM controller.

41.9.1.7 Access Protection

On the CM subsystem, access protection to all the RAMs are done via master specific memory protection unit (MPU) and not in the SRAM controller. Each master on the CM subsystem has a dedicated MPU to filter the accesses. For MSG RAMs, in addition to the MPU, there is logic in-built in the controller to prevent accesses such as fetch or write (if not allowed).

41.9.1.8 Memory Error Detection, Correction and Error Handling

As mentioned in earlier sections, some RAMs on CM subsystem are ECC-protected and some are parity. ROMs are parity-protected. The ECC scheme used is Single Error Correction Double Error Detection (SECDED). The parity scheme used is even parity. ECC/Parity will cover the data bits stored in memory as well as address. ECC/Parity calculation is done inside the memory controller module and then calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit data, there will be three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

The fllowing diagram shows how a word is stored in memory.

Figure 41-8. Content of each memory location for ECC memories

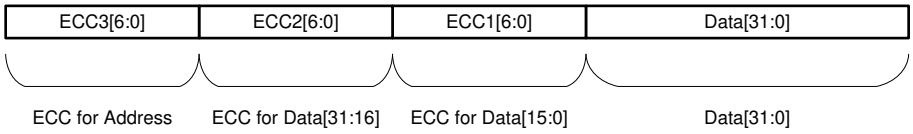


Figure 41-9. Content of each memory location for Parity memories

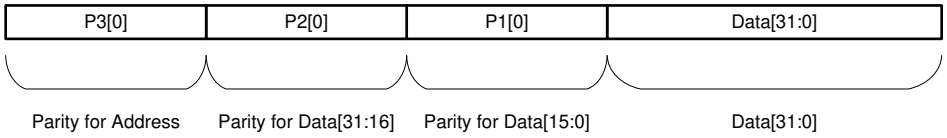


41.9.1.8.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in the case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable errors and uncorrectable errors.

The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are always uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent double-bit error due to another single-bit error at the same memory address.

Size of write access initiated by bus masters on CM subsystem can be byte or half-word or full word. Since ECC/Parity is calculated for 16-it word, in case of byte write access memory controller performs Read-Modify-Write operation (read 16-bit from RAM block, modify the specific byte with new data, calculate ECC/parity for new data and write the data and ECC/parity back into RAM block).

41.9.1.8.2 Error Handling

Two types of error gets generated by memory controller, correctable error and uncorrectable.

On correctable error, the following actions are performed by the memory controller:

- Correct the data and return corrected data to the master
- The address, for which the error occurred, gets latched into the address status register
- Bus master info is captured
- Correctable error counter is incremented
- Interrupt is generated if correctable error count exceeded user programmed threshold

The user needs to configure the correctable error threshold register based on the system requirements. On uncorrectable error, the following actions are performed by the memory controller – incorrect data is returned to the Master and an NMI is generated to Cortex-M4. The address for which the error occurred gets latched into the address status register, and a flag gets set.

- NMI is generated to Cortex-M4 and incorrect data is returned to the master
- The address, for which the error occurred, gets latched into the address status register
- Bus master info is captured

Table 41-7. Error Handling of memories

Access Type	Error	Action
Write (16bit/32bit access)	NA	NA
Write (byte access) (Controller performs Read-Modify-Write)	Uncorrectable error on read data	Write is aborted, NMI gets generated
	Correctable error on data (only ECC RAMs)	• RMW operation is performed on corrected data. • Correctable error counter is incremented. Interrupt is generated when correctable error counter exceeds user programmed threshold value. • Corrected Data is written back to the memory.
Read	Correctable error	• Correctable error counter is incremented. Interrupt is generated when correctable error counter exceeds user programmed threshold value. • Corrected data is written back to the memory.
	Uncorrectable error on read Data	NMI is generated, data (could be wrong) is returned to bus master.

Note – ECC/Parity errors are ignored for debug access (no NMI/interrupt for error during debug access). Even though an error is not generated for debug access, the memory controller always returns the corrected data for correctable errors.

41.9.1.8.3 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic are part of safety critical logic, safety applications may need to ensure that the logic is always working fine (during run time also). To enable this, a test mode is provided. Using test mode, the user can inject the ECC/parity error by modifying data bits (controller does not update the ECC/parity bits) or the ECC/parity bits directly. Since the memory map for ECC/parity bits and data bits are the same, a different test mode is provided for accessing data and ECC/parity bits. The user programs different test modes based on the usage.

The following tables show the bit mapping for the ECC/Parity bits when they are read in RAMTEST mode, using their respective addresses.

Table 41-8. Mapping of ECC bits in Read Data from ECC/parity address map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

Table 41-9. Mapping of parity bits in Read Data from ECC/parity address map

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

41.9.1.8.4 ROM Test

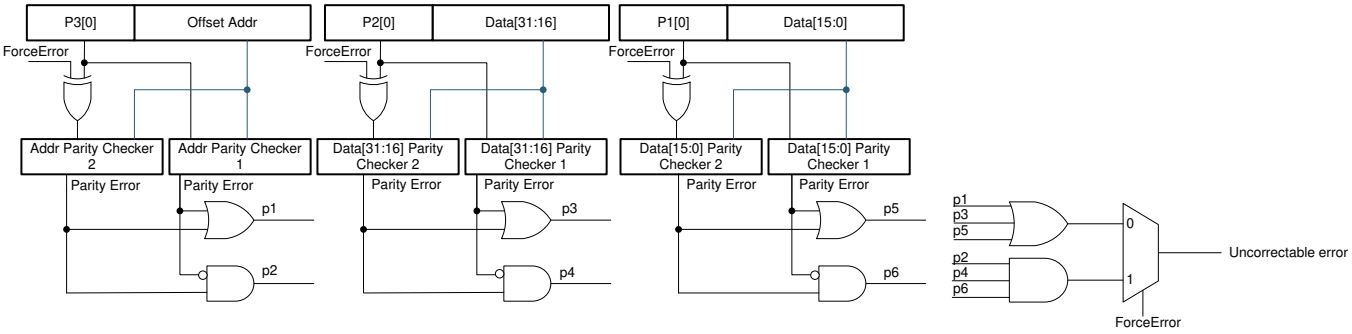
ROMs are read only memory; unlike RAMs, data or parity bits cannot be modified to introduce errors for diagnostic coverage of parity checking logic. The following method is used to check health of parity checking logic in ROMs.

- Add duplicate parity check logic and feed the same data into duplicate parity checker
- Generate uncorrectable error if the parity check status of these two separate parity checkers do not match

The probability of both circuits having fault is unlikely ; therefore, parity errors will be certainly detected.

To generate the error, a test bit FORCE_ERROR is added. When the FORCE_ERROR bit is set, the parity bit going to one of party checker is inverted, thereby introducing an uncorrectable error. An uncorrectable error is generated only if there is an error on all parity checker, that is, address, data [15:0] and data [31:16]. This will ensure that all three parity checkers are working as expected.

Figure 41-10. ROM parity checking logic



41.9.1.9 RAM initialization

After power-up, RAM comes up with random data and reading memories may result in an error. To ensure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/parity bits, accordingly. This can be initiated by setting the INIT bit to '1' for the specific RAM block in INIT registers. To check the status of RAM initialization, software must poll for the INITDONE bit to be set for that RAM block in the INITDONE. Unless this bit gets set, no access should be made to that RAM memory block.

NOTE: None of the masters should access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization will not happen correctly.

41.10 Memory Protection Unit (MPU)

The CM subsystem has multiple masters accessing the memory blocks and peripherals. Below is the list of masters on the CM subsystem:

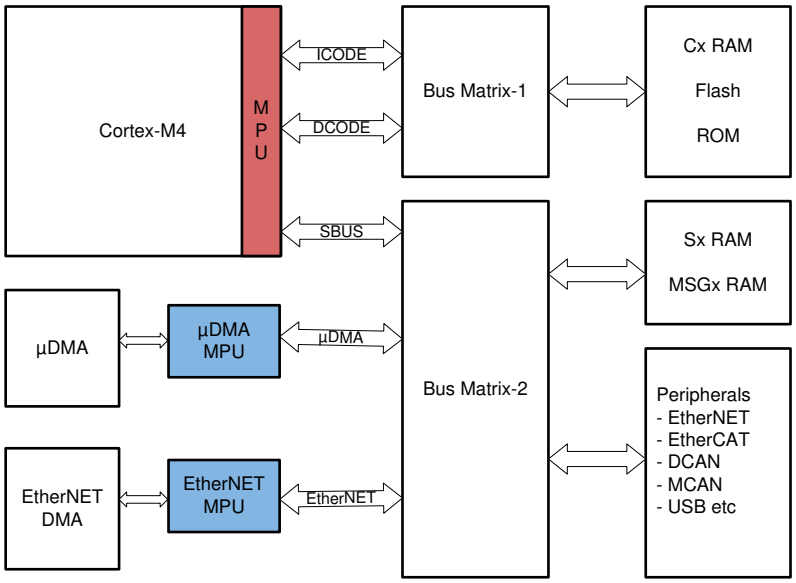
- Cortex-M4
- uDMA
- EtherNET DMA

In a multi-master system, it is important to have a protection mechanism to prevent unauthorized access to critical code, data, or peripherals from different masters or threads. This protection mechanism will:

- Prevent a process or a task from accessing memory that is not allocated to it.
- Protect Cortex-M4 code from unintended corruption by other bus masters on the CM subsystem
- Protect stack corruption by other bus masters on CM systems

Cortex-M4 has ARM native MPU (Cortex-M4 MPU) which provides such protection (see the Memory Protection Unit chapter of the *ARM® Cortex®-M4 Processor Technical Reference Manual*). For other masters (uDMA and Ethernet DMA), a generic memory protection unit (CM-MPU) has been provided which users can configure based on the use case, to enable the protection. Basically, one MPU for each master is provided to protect the accesses from that master. See Section 41.9 for more details.

Figure 41-11. CM Block Diagram



41.10.1 Functional Desciption

The CM-MPU is used for access protection on uDMA and EtherNET master bus. The MPU divides the memory map into a number of regions. Each region has programmable start address, size, and access permissions.

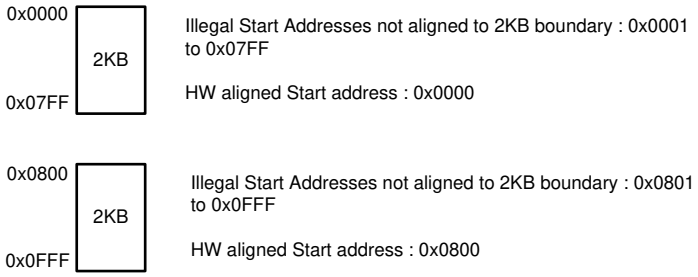
The following are the access protections supported:

- Read-only access
- Full access - both Read and Write accesses are allowed
- No access - Read and Write accesses are not allowed

An access protection violation will result in a bus fault to the master and access info is captured in the MPU register for debug purposes.

Each MPU has a maximum of eight regions. The start address of a region must be aligned to its size. For example, a 32KB region must be aligned to a multiple of 32KB address at 0x0000_0000 or 0x0000_8000. If the start address of the region is not boundaryaligned to region size, that is, the start address is not a divisible size of the region, then hardware automatically aligns the region start address by truncating the number of LSBs, depending on region size. Following is an example of an unaligned start address with a region size of 2KB.

Figure 41-12. Unaligned Start Address

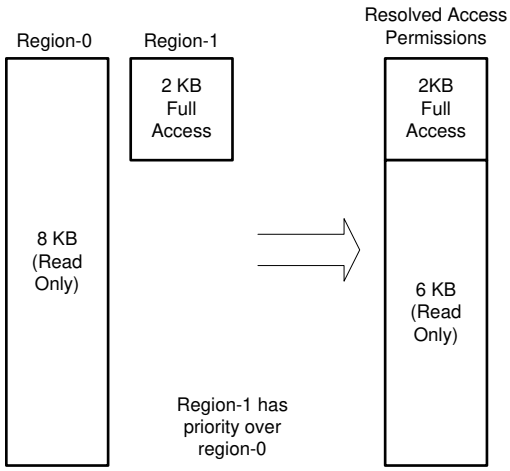


The minimum size of the region is limited to 1KB. Each region can be enabled or disabled in the application based on the use case.

41.10.2 Overlapping Regions

When defining the start address and size for different regions, the user can overlap the regions; in that case a fixed priority scheme is used to resolve the access protection. Region 7 is the highest priority and regsion 0 is lthe owest priority. This feature is useful to define different set of access permissions for a part of analready defined bigger region.

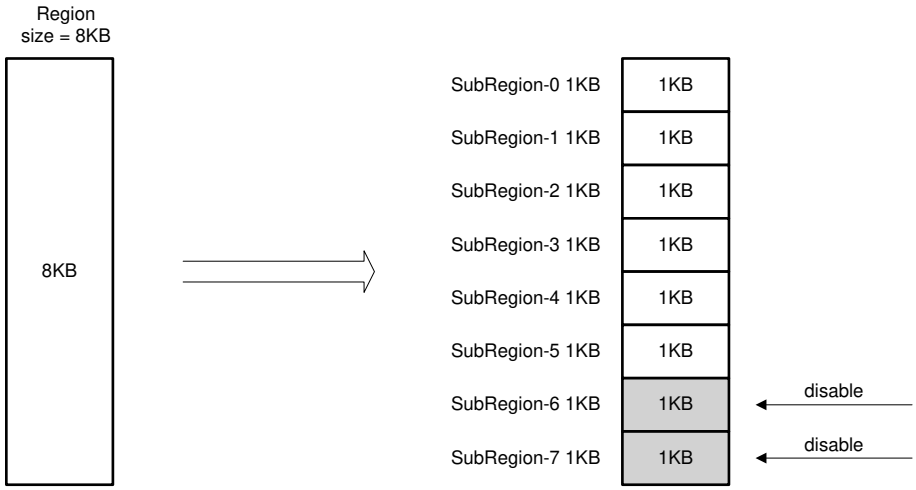
Figure 41-13. Overlapping Regions



41.10.3 Sub-Regions

Each region can be further divided into eight equal sub regions and each sub-region can be independently enabled or disabled in application code. When a sub-region is disabled, access permissions do not apply to that region. Disabled sub-regions are similar to undefined regions. This feature is useful when a part of the region is to be excluded while running a specific section of application.

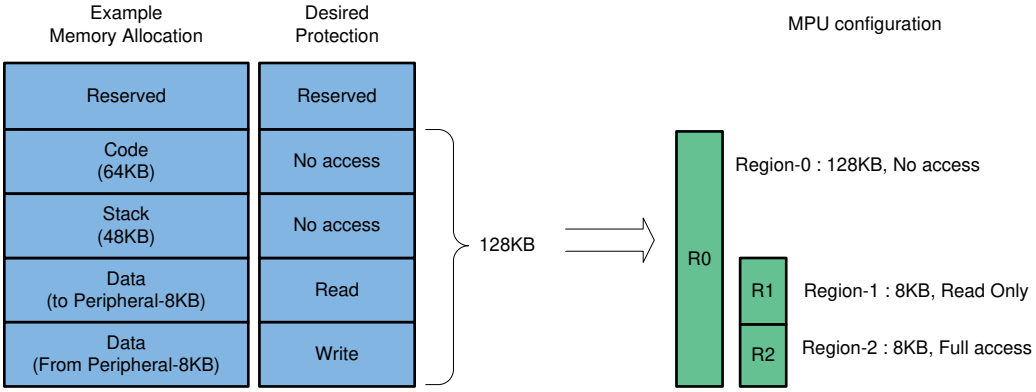
Figure 41-14. Sub-Regions



41.10.4 Programmers Model

The primary purpose of a uDMA MPU is to protect code, stack and peripherals from unintended uDMA accesses. In the following example memory map, the expectation is to not have any µDMA access to code and stack section; only read access to one section of peripheral region and full access to other sections of peripheral.

Figure 41-15. Programmers Model Memory Map



There are two ways to define the MPU region.

1. Define three different (independent) regions for no access, read access and full access memory map section.
2. Define no access for full memory map section and then define other region which overlaps to the ist region and have different protections attribute. For this Region-0 is defined as a no-access region with full memory map and then Region-1 is defined as read-only and Region-2 is defined as full-access regions. Since Region 1 and Region 2 have higher priority over Region-0, their protection attribute will override Region-0 protection attribute.

41.11 Debug and Trace

The CM subsystem includes Cortex-M4 which has its own debug interface via the Debug Access Port (DAP). Users can connect to the CM subsystem in parallel to the CPU1 and CPU2 core and perform a debug. Users must also release the reset for the CM subsystem before connecting to the debugger. The CCS gel file on CPU1 will take care of this if CPU1 is connected to CCS.

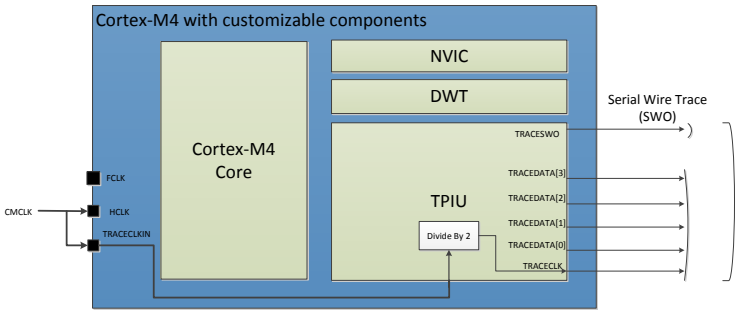
41.11.1 Trace Port Interface Unit

Trace capability from Cortex-M4 will be supported on the CM subsystem. There are two trace interfaces supported on Cortex-M4:

- Single wire trace, which follows a UART protocol and is asynchronous.
- Five-pin (four data pins and one clock pin) and parallel trace.

Both the options are supported on this device. The following diagram illustrates the high -evel clock and signal hookup to and from Trace Port Interface Unit.

Figure 41-16. Debug Trace



The following table lists the key attributes of the two trace data export mechanisms. Please Refer to the *Arm Architecture Reference Manual* for further details about TPIU and trace mechanisms.

Table 41-10. Key Attributes of Trace Data Export

Attribute Parallel Trace	Serial Wire Trace	Parallel Trace
Protocol	UART Protocol/Manchester encoded data stream	Trace Data changes on both edges of TRACECLK.
Data throughput rate	Frequency(CMHCLK)/(TPIU_ACPR + 1)	Frequency(CMHCLK)/2

You must configure the GPIO mux to select a trace function on the GPIO pin to use it.

41.12 CM-SysCtrl Registers

This section describes the Connectivity Manager System Control Registers.

41.12.1 CM-SysCtrl Base Addresses

Table 41-11. CM SYSCTRL Base Address Table (CM)

DriverLib Name	Base Address	uDMA Access	Ethernet DMA Access
CMMEMCFG_BASE	0x400F_E000	-	-

A0h	PERI_MEM_TEST_LOCK	Peripheral Memory Test Lock Register		Go
A4h	PERI_MEM_TEST_CONTROL	Peripheral Memory Test control Register	Lock Protection	Go

Complex bit access types are encoded to fit into small table cells. Table 41-13 shows the codes that are used for access types in this section.

Table 41-13. CM_MEMCFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.2.1 CxLOCK Register (Offset = 0h) [reset = 0h]

CxLOCK is shown in Figure 41-17 and described in Table 41-14.

41.12.3 CM_MEMORYDIAGERROR_REGS Registers

Table 41-31 lists the CM_MEMORYDIAGERROR_REGS registers. All register offset addresses not listed in Table 41-31 should be considered as reserved locations and the register contents should not be modified.

Table 41-31. CM_MEMORYDIAGERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	DIAGERRFLG	Error Flag Register		Go
8h	DIAGERRCLR	Error Flag Clear Register		Go
Ch	DIAGERRADDR	Read Error Address		Go

Complex bit access types are encoded to fit into small table cells. Table 41-32 shows the codes that are used for access types in this section.

Table 41-32. CM_MEMORYDIAGERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.3.1 DIAGERRFLG Register (Offset = 0h) [reset = 0h]

DIAGERRFLG is shown in Figure 41-34 and described in Table 41-33.

Return to the Summary Table.

CuDMAEADDR																															
R-0h																															

Table 41-56. CuDMAEADDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CuDMAEADDR	R	0h	This register captures the address location at which uDMA read or write access resulted in correctable ECC error. Reset type: CM.RESETn

41.12.4.20 CERRCNT Register (Offset = C0h) [reset = 0h]

CERRCNT is shown in Figure 41-56 and described in Table 41-57.

Return to the Summary Table.

Correctable Error Count Register

Figure 41-56. CERRCNT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CERRCNT																															
R/W-0h																															

Table 41-57. CERRCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CERRCNT	R/W	0h	This register holds the count of how many times correctable error occurred. It will stop counting once threshold value is reached Counter is reset to 0x0 automatically upon clearing correctable interrupt flag i.e. by writing '1' to CEINTCLR[CEINTCLR] Reset type: CM.RESETn

41.12.4.21 CERRTHRES Register (Offset = C4h) [reset = 0h]

CERRTHRES is shown in Figure 41-57 and described in Table 41-58.

Return to the Summary Table.

Correctable Error Threshold Value Register

Figure 41-57. CERRTHRES Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CERRTHRES																															
R/W-0h																															

Table 41-58. CERRTHRES Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CERRTHRES	R/W	0h	When value in CERRCNT register is greater than or equal to the value configured in this register, correctable interrupt gets generated if enabled. Reset type: CM.RESETn

41.12.4.22 CEINTFLG Register (Offset = C8h) [reset = 0h]

CEINTFLG is shown in Figure 41-58 and described in Table 41-59.

Return to the Summary Table.

60h	CMCLKSTOPACK0	Peripheral Clock Stop Ackonwledge Register 0		Go
64h	CMCLKSTOPACK1	Peripheral Clock Stop Ackonwledge Register 1		Go
68h	CMCLKSTOPACK2	Peripheral Clock Stop Ackonwledge Register 2		Go
E0h	MCANWAKESTATUS	MCAN Wake Status Register		Go
E4h	MCANWAKESTATUSCLR	MCAN Wake Status Clear Register		Go
100h	CMECATCTL	CM etherCAT control register		Go
1F4h	PALLOCATESTS	Status of PALLOCATE register.		Go
1F8h	CMRESCCLR	CM Reset Cause Status Clear Register		Go
1FCh	CMRESC	CM Reset Cause Status Register		Go
200h	CMSYSCTLLOCK	Locks the configuration registers of CM System control		Go

Complex bit access types are encoded to fit into small table cells. Table 41-64 shows the codes that are used for access types in this section.

Table 41-64. CMSYSCTL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 41-64. CMSYSCTL_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.5.1 CMPCLKCR0 Register (Offset = 0h) [reset = 0h]

CMPCLKCR0 is shown in Figure 41-62 and described in Table 41-65.

Return to the Summary Table.

41.12.6 CM_CPUTIMER_REGS Registers

Table 41-84 lists the CM_CPUTIMER_REGS registers. All register offset addresses not listed in Table 41-84 should be considered as reserved locations and the register contents should not be modified.

Table 41-84. CM_CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	Timer counter register	EALLOW	Go
4h	PRD	Timer period register	EALLOW	Go
8h	TCR	Timer control register	EALLOW	Go
Ch	TPR	Timer prescaler register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 41-85 shows the codes that are used for access types in this section.

Table 41-85. CM_CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.6.1 TIM Register (Offset = 0h) [reset = FFFFh]

TIM is shown in Figure 41-81 and described in Table 41-86.

Return to the Summary Table.

System Control & Status Register

RESERVED		TRB	TSS	RESERVED			
R-X		R-0/W1S-0h	R/W-0h	R-X			

Table 41-88. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	X	Reserved
15	TIF	R/W1S	0h	Timer Interrupt Flag. This flag gets set when the timer decrements to zero. This bit can be cleared by software writing a 1, but it can only be set by the timer reaching zero. Writing a 1 to this bit will clear it, writing a zero has no effect. Reset type: CM.RESETn
14	TIE	R/W	0h	Timer Interrupt Enable. If the timer decrements to zero, and this bit is set, the timer will assert it's interrupt request. Reset type: CM.RESETn
13-12	RESERVED	R	X	Reserved
11	FREE	R/W	0h	If this bit is set then on a debug halt of CM4, timer would continute to decrement and generate periodic interrupts. If this bit is 0, counter behavior under debug halt condition is determined by TCR.SOFT bit. Reset type: CM.RESETn
10	SOFT	R/W	0h	If the TCR.FREE bit is 0 and SOFT bit is: 0 : On a debug halt of CM4, timer will stop counting immediately (Hard Stop) 1 : On a debug halt of CM4, timer will stop counting upon reaching 0 and generating the interrupt (Soft Stop) If the TCR.FREE bit is 1 then SOFT bit has no impact in timer behavior. Reset type: CM.RESETn
9-6	RESERVED	R	X	Reserved
5	TRB	R-0/W1S	0h	Timer Reload bit. When a 1 is written to TRB, the TIM is loaded with the value in the PRD, and the pre-scaler counter (PSC) is loaded with the value in the timer divide-down register (TDDR). The TRB bit is always read as zero Reset type: CM.RESETn

Table 41-88. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	TSS	R/W	0h	Timer stop status bit. TSS is a 1-bit flag that stops or starts the timer. To stop the timer, set TSS to 1. To start or restart the timer, set TSS to 0. At reset, TSS is cleared to 0 and the timer immediately starts. Reset type: CM.RESETn
3-0	RESERVED	R	X	Reserved

41.12.6.4 TPR Register (Offset = Ch) [reset = 0h]

TPR is shown in Figure 41-84 and described in Table 41-89.

Return to the Summary Table.

Timer prescaler register

Figure 41-84. TPR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSCH								TDDRH								PSCL								TDDRL							
R-0h								R/W-0h								R-0h								R/W-0h							

Table 41-89. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	PSCH	R	0h	See description of PSCL above Reset type: CM.RESETn
23-16	TDDRH	R/W	0h	See description of TDDRL above Reset type: CM.RESETn
15-8	PSCL	R	0h	Timer Pre-Scale Counter. These bits hold the current pre-scale count for the timer. For every timer clock source cycle that the PSCH:PSCL value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer pre-scaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSCL is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSCL can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSCL is set to 0. Reset type: CM.RESETn
7-0	TDDRL	R/W	0h	Timer Divide-Down. Every (TDDRH:TDDRL + 1) timer clock source cycles, the timer counter register (TIM) decrements by one. At reset, the TDDRH:TDDRL bits are cleared to 0. If you want to increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDRL bits. When the prescaler counter (PSCH:PSCL) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDRL reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDRL also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: CM.RESETn

41.12.7 MPU_REGS Registers

Table 41-90 lists the MPU_REGS registers. All register offset addresses not listed in Table 41-90 should be considered as reserved locations and the register contents should not be modified.

Table 41-90. MPU_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	MPU_CONTROL_REG	MPU control regster	Privilege mode	Go
20h	ACC_VIO_INTEN	Access violation interrupt enable	Key based protection	Go
24h	ACC_VIO_FLAGS	Access violation flag register		Go
28h	ACC_VIO_FLAGS_SET	Acesss violation set register	Key based protection	Go
2Ch	ACC_VIO_FLAGS_CLR	Access violation clear register	Key based protection	Go
30h	ACC_VIO_ADDR_REG	Access violation address register		Go
40h	REGION0_STARTADDRESSS	Region 0 start address register	Privilege mode	Go
44h	REGION0_CONFIG	Region 0 configuration register	Privilege mode	Go
48h	REGION1_STARTADDRESSS	Region 1 start address register	Privilege mode	Go
4Ch	REGION1_CONFIG	Region 1 configuration register	Privilege mode	Go
50h	REGION2_STARTADDRESSS	Region 2 start address register	Privilege mode	Go
54h	REGION2_CONFIG	Region 2 configuration register	Privilege mode	Go
58h	REGION3_STARTADDRESSS	Region 3 start address register	Privilege mode	Go

78h	REGION7_STARTADDRESSS	Region 7 start address register	Privilege mode	Go
7Ch	REGION7_CONFIG	Region 7 configuration register	Privilege mode	Go

Complex bit access types are encoded to fit into small table cells. Table 41-91 shows the codes that are used for access types in this section.

Table 41-91. MPU_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 41-91. MPU_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.7.1 MPU_CONTROL_REG Register (Offset = 0h) [reset = 0h]

MPU_CONTROL_REG is shown in Figure 41-85 and described in Table 41-92.

Return to the Summary Table.

41.12.8 CM_NMI_INTRUPT_REGS Registers

Table 41-114 lists the CM_NMI_INTRUPT_REGS registers. All register offset addresses not listed in Table 41-114 should be considered as reserved locations and the register contents should not be modified.

Table 41-114. CM_NMI_INTRUPT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CMNMICFG	CM NMI Configuration Register		Go
4h	CMNMIFLG	CM NMI Flag Register		Go
8h	CMNMIFLGCLR	CMNMI Flag Clear Register		Go
Ch	CMNMIFLGFRC	CMNMI Flag Force Register		Go
10h	CMNMIWDCNT	CMNMI Watchdog Counter Register		Go
14h	CMNMIWDPRD	CMNMI Watchdog Period Register		Go
18h	CMNMISHDWFLG	CMNMI Shadow Flag Register		Go

Complex bit access types are encoded to fit into small table cells. Table 41-115 shows the codes that are used for access types in this section.

Table 41-115. CM_NMI_INTRUPT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.8.1 CMNMICFG Register (Offset = 0h) [reset = 0h]

CMNMICFG is shown in Figure 41-107 and described in Table 41-116.

Return to the Summary Table.

Table 41-117. CMNMIFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RESERVED	R	0h	Reserved
6	ECATNMI	R	0h	0 No reset request from EtherCAT IP. 1 NMI generated from EtherCAT IP. No further NMI pulses are generated until this flag is cleared by the user. Reset type: CM.RESETn
5	WWDNMI	R	0h	CM Windowed Watchdog NMI Flag: This bits indicates if CM watch dog generated an NMI. 0 CM WWD has not generated an NMI 1 CM WWD has generated an NMI Reset type: CM.RESETn
4	MCANUNCERR	R	0h	MCAN Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on an access MCAN message RAM, and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the CMNMIFLGCLR register or by an XRSn reset: 0,No CM4 Flash uncorrectable error condition pending 1,CM4 Flash uncorrectable error condition generated Reset type: CM.RESETn
3	FLUNCERR	R	0h	Flash Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on a CM4 Flash access and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the CMNMIFLGCLR register or by an XRSn reset: 0,No CM4 Flash uncorrectable error condition pending 1,CM4 Flash uncorrectable error condition generated Reset type: CM.RESETn
2	MEMUNCERR	R	0h	RAM/ROM Uncorrectable Error NMI Flag: This bit indicates if an uncorrectable error occurred on a RAM (Including peripheral RAMs)/ROM access (by any master) and that condition is latched. This bit can only be cleared by the user writing to the corresponding clear bit in the CMNMIFLGCLR register or by an XRSn reset: 0,No RAM/ROM uncorrectable error condition pending 1,RAM/ROM uncorrectable error condition generated Reset type: CM.RESETn

Table 41-117. CMNMIFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	CLOCKFAIL	R	0h	Clock Fail Interrupt Flag: These bits indicates if the CLOCKFAIL condition is latched. These bits can only be cleared by the user writing to the respective bit in the CMNMIFLGCLR register or by an XRSn reset: 0,No CLOCKFAIL Condition Pending 1,CLOCKFAIL Condition Generated Reset type: CM.RESETn
0	NMIINT	R	0h	NMI Interrupt Flag: This bit indicates if an NMI interrupt was generated. This bit can only be cleared by the user writing to the respective bit in the CMNMIFLGCLR register or by an XRSn reset: 0 No NMI Interrupt Generated 1 NMI Interrupt Generated No further NMI interrupts pulses are generated until this flag is cleared by the user. Reset type: CM.RESETn

41.12.8.3 CMNMIFLGCLR Register (Offset = 8h) [reset = 0h]

CMNMIFLGCLR is shown in Figure 41-109 and described in Table 41-118.

Return to the Summary Table.

Table 41-120. CMNMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set. Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway. The counter is clocked at the CMCLK rate. Reset type: CM.RESETn

41.12.8.6 CMNMIWDPRD Register (Offset = 14h) [reset = FFFFh]

CMNMIWDPRD is shown in Figure 41-112 and described in Table 41-121.

Return to the Summary Table.

Table 41-121. CMNMIWDPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to any of the fields of this register will suceed only if a value 0x9238 appears on the KEY field. Reset type: CM.RESETn
15-0	NMIWDPRD	R/W	FFFFh	NMI Watchdog Period: This 16-bit value contains the period value at which a reset is generated when the watchdog counter matches. At reset this value is set at the maximum. The software can decrease the period value at initialization time. Note:If a PERIOD value is written that is smaller than the current counter value, the counter will continue counting until it overflows and starts counting up again from 0. After the overflow, once the COUNTER value equals the new PERIOD value, an NMIRS is forced which resets the watchdog counter. Reset type: CM.RESETn

41.12.8.7 CMNMISHDWFLG Register (Offset = 18h) [reset = 0h]

CMNMISHDWFLG is shown in Figure 41-113 and described in Table 41-122.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 41-124 shows the codes that are used for access types in this section.

Table 41-124. NVIC Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 41-124. NVIC Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

41.12.9.1 NVIC_ISER0 Register (Offset = 100h) [reset = 0h]

NVIC_ISER0 is shown in Figure 41-114 and described in Table 41-125.
